# INTRODUCTION

## Contents

The thesis addresses nonparametric Bayesian methods in robotic vision. Nonparametric Bayesian models can be simultaneously employed to perform inference over the number of entities observed and over the shape or nature of these entities. This chapter introduces nonparametric Bayesian models, the research methodology based on the Bayesian methodology, the main contribution towards robotic vision, and the general organization of the thesis.

## Outline

The scope of thesis is to apply nonparametric Bayesian methods to robotic vision (Section 1.1). Bayesian nonparametric models define entities together with noise in such a way that inference can be performed in an optimal manner (Section 1.2). Particular problems in robotic vision that can benefit from Bayesian nonparametric methods are formulated and detailed (Section 1.3). The research methodology is described (Section 1.4). Our main contribution is to introduce nonparametric Bayesian models in robotic vision (Section 1.5). At the end of this chapter the organization of the thesis is given (Section 1.6).

## 1.1 Scope of the Thesis

In the thesis, modern Bayesian nonparametric methods are used to answer long-standing questions within computer vision and robotics. The following three challenging questions are typical examples. Is there a Bayesian form of line detection rather than applying the traditional Hough transform? Which of the nonparametric Bayesian priors can be used to detect multiple features simultaneously? What are efficient inference methods for these priors?

The scope of the thesis is the transfer of knowledge on Bayesian nonparametrics to well-described application domains. It will not establish a new body of work around a new family

of stochastic processes. The detailed application of complex models towards robotic vision is expected to help and encourage people in entirely different application domains, such as collaborative filtering, search engine optimization, and audio processing. All these different applications do not always need dedicated algorithms, but do deserve and can exploit the same optimal general inference techniques from Bayesian nonparametrics.

## 1.2 Bayesian Nonparametrics

In robotic vision (computer vision and depth perception) traditionally custom-made algorithms have been developed for a given task. There are specific methods to detect corners (e.g., Förstner and Gülch, 1987; Harris and Stephens, 1988; Shi and Tomasi, 1994), to detect edges (e.g., Sobel, 1970; Canny, 1986), to detect features (e.g., Hough, 1962), and to describe features (e.g., Lowe, 1999; Dalal and Triggs, 2005; Bay et al., 2006).

On the one hand, it is desirable that such sophisticated methods are generalizable to other application domains. On the other hand, it is important to take particular information about an application domain into account. The methods described in the previous paragraph are limited to their specific task. An example of limited generalizability can be found in the Hough transform. The Hough transform can be used to detect lines, but the way inference is performed in the algorithm does limit its application to basic forms of object detection. An example of limited specificity can be found in linear regression. Linear regression does not take into account real-world statistics.

Both generalization and specificity are formalized by a Bayesian model. A Bayesian model is general because it can be solved with general inference methods. One of such general inference methods is a Markov-Chain Monte Carlo method. It does not know anything about real-world statistics. A Bayesian model is also specific in that it can incorporate application-specific know-how by the definition of priors.

Typical problems in robotic vision will be about the recognition of several objects, multiple shapes, or objects that have multiple parts. Models that represent such objects do not have knowledge about the number of such objects, shapes, or parts. To incorporate application-specific know-how on the number of objects it is possible to define a prior that assigns a probability to this quantity. The number of objects can even be potentially infinite. The Bayesian models that define a prior on the number of objects, shapes, or parts are called nonparametric Bayesian models. This means that in contrast with conventional methods such as  $k$ -means clustering (Forgy, 1965; Lloyd, 1982) the number of objects does not need to be predefined.

## 1.3 Problem Statement and Research Questions

Many methods in robotics - and in particular in robotic vision - have been developed in times where computational resources were limited. Then, highly optimized algorithms have been developed, leveraging peculiarities of the application domain. Recent advances in Bayesian

208 methods, both with respect to concept development, as well as computational efficient so-  
209 lution strategies, now open up new ways to solve old problems. However, extending only  
210 the old methods themselves would lead to ad-hoc solution strategies that will miss benefits  
211 from potential optimal and more widely applicable algorithms.

212 This observation leads us to the formulation of our problem statement (PS).

213       **PS:**     *How can robotic problems effectively be generalized and their structure  
                  exploited in a wider Bayesian framework?*

214 The problem statement is rather general. In our research, we focus on robotic vision, in the  
215 form of point cloud recognition and depth perception. In particular, we look at objects, lines,  
216 line segments, and more complex shapes.

217 The problem statement is divided into three research questions (RQs).

**RQ 1**   How can we estimate the number of objects simultaneously with the  
                  fitting of these objects?

218       **RQ 2**   How can we estimate the number of lines simultaneously with line fitting  
                  in computer vision?

**RQ 3**   How can we recognize more general 3D objects?

## 219   1.4   Research Methodology

220 The research methodology advocated in the thesis follows the Bayesian methodology (cf.  
221 Savage, 1972; Jaynes, 2003). So, our research methodology exists out of two phases. In the  
222 first phase a Bayesian model is defined. This model exists of (1) a definition of parameters  
223 and relations between these parameters, (2) a definition of the noise, and (3) the data. In  
224 the second phase, the Bayesian method dictates all remaining unknowns, from the number  
225 of parameters to the values of the parameters. To perform Bayesian inference efficiently new  
226 methods are required if the model is complex (as is in the case of robotic vision).

227 The Bayesian methodology aims to establish the rationale for practical questions. The fol-  
228 lowing two questions are clear examples.

- 229       ◦ If we observe a single point in an image, can we expect it to be part of a line?
- 230       ◦ If we have two lines and we live in a world with squares, what are we able to infer?

231 The two questions tap into our capabilities to define models that makes our prior knowledge  
232 explicit. Moreover, if we are able to quickly assign (1) points to segments, (2) segments to  
233 lines, (3) objects to categories, we can enrich it with all corresponding group properties  
234 without the need to have them observed for this individual.

235 In robotic vision we take as an example the task of line detection. Both the Hough transform  
236 (Hough, 1962) and the RANSAC method (Bolles and Fischler, 1981) do detect lines, but they  
237 do not explicitly take noise into account. By applying Bayesian methodology to these tasks,  
238 the inference method becomes optimal in an information-theoretic sense. Also frequentist  
239 statisticians agree that nonparametric Bayesian models are consistent in the sense that they  
240 approach the underlying true distribution (Wasserman, 1998). There is no need to search  
241 for another method to infer lines in a line detection task. If someone would find a method  
242 that outperforms a Bayesian method it is either (1) because the signal or noise has not been  
243 correctly modeled after all, or (2) because the method overfits with respect to the available  
244 data. If approximations are used with respect to optimal Bayesian inference (either varia-  
245 tional approximations or Markov-Chain Monte Carlo), there are theoretical guarantees on  
246 convergence.

247 A well known problem with nonparametric Bayesian models is the curse of dimensionality.  
248 Compared to maximum likelihood methods or other non-probabilistic methods that do not  
249 take noise into account at all, the nonparametric Bayesian models require significant com-  
250 putational resources. Our research methodology first establishes the correct models, even  
251 if solving them seems computationally infeasible. Our approach is to develop subsequently  
252 approximations using more sophisticated samplers, so that the theoretical guarantees on  
253 convergence are preserved.

254 Due to the fact that the models are optimal by construction, there are no experiments re-  
255 quired to address the optimality in particular. However, experiments are still required to  
256 establish whether the models make sense. Yet, the methodology does also have limitations.  
257 For instance, we will not search over different noise models and limit priors to a particular  
258 hierarchical level.

## 259 1.5 Main Contribution

260 Our contribution to robotic vision can be subdivided into three parts that correspond with  
261 the three research questions.

262 The first part addresses the problem of inference about objects from a nonparametric Bayes-  
263 ian perspective. Contemporary methods in robotic vision do not allow for astute statements  
264 about their performance. In practice, this means that when using computer vision to detect  
265 cells under a microscope, someone cannot be confident about the number of detected cells.  
266 An autonomous cleaning robot in a supermarket cannot be confident about the aisle it is driv-  
267 ing into. To be able to properly take into account models and uncertainty simultaneously,  
268 Bayesian models have found mainstream adoption. State-of-the-art Bayesian methods that  
269 reason about the number of objects alongside object models are a recent object of study (cf.  
270 Ferguson, 1973; Hjort, 1990; Lijoi and Prünster, 2010; Joho et al., 2011). The thesis applies  
271 such nonparametric Bayesian models towards the applications of robotic vision and depth  
272 perception. Models such as the infinite line model and the infinite line segment model are  
273 introduced.

274 The second part addresses the problem of high-dimensional data. To efficiently sample  
275 more complex geometric structures, new MCMC (Markov-Chain Monte Carlo, Section 2.3.4)  
276 methods are required. The thesis introduces such an MCMC sampler, namely a new Split-  
277 Merge sampler, and applies it to complex geometric structures.

278 The third part addresses more complex robotic vision problems, in the form of object recog-  
279 nition of point clouds in 3D. It combines nonparametric Bayesian inference with models  
280 from deep learning.

## 281 1.6 Organization of the Thesis

282 **Chapter 1** (this chapter) introduces the problem of contemporary methods in computer  
283 vision and depth perception. Due to the fact that these methods are not optimal  
284 by construction, it is hard to articulate how they perform. The need for a Bayesian  
285 methodology is sketched briefly. The problem statement and the research questions  
286 are formulated. Moreover, the research methodology is described and the organization  
287 of the thesis is outlined.

288 **Chapter 2** describes (1) probability theory using measure theory, (2) random measures  
289 known as random processes of which five are described as nonparametric Bayesian  
290 models, and (3) six inference methods that infer model parameters of such nonpara-  
291 metric Bayesian models given the data. It is followed by a discussion that indicates  
292 which parts will be most useful for chapters 3 and 4.

293 **Chapter 3** examines a first nonparametric Bayesian model, i.e., the infinite line model. The  
294 infinite line model represents a countably infinite set of lines. Gibbs sampling is used  
295 to perform simultaneous inference over (1) the number of lines and (2) line parameter  
296 values such as slope and intercept.

297 **Chapter 4** examines a second nonparametric Bayesian model, i.e., the infinite line segment  
298 model. The infinite line segment model represents a countably infinite set of line  
299 segments. A split-merge MCMC sampling method is used to perform simultaneous  
300 inference over (1) the number of line segments and (2) line segment parameter values  
301 such as slope, intercept, and segment size. Chapters 2 to 4 answer the first research  
302 question.

303 **Chapter 5** investigates a new MCMC method, the Triadic Split-Merge sampler. It is tailored  
304 to clustering problems and accelerates inference of the models in Chapters 3 and 4.  
305 This chapter answers the second research question.

306 **Chapter 6** examines a third nonparametric Bayesian model, particularly aimed at volumet-  
307 ric inference. This chapter answers the third research question.

308 **Chapter 7** applies the hierarchical sampling method to the domain of recommender en-  
309 gines. It estimates simultaneously the number of user types with a fitting procedure  
310 for the individual user. I want to change this chapter to something relevant to point  
311 clouds.

312 **Chapter 8** discusses the relevance of the developed models and inference methods. The  
313 answers to the research questions are discussed. Then the problem statement is an-  
314 swered and conclusions are formulated. Finally, recommendations are given and fu-  
315 ture research is envisaged.

In robotics depth sensors generate point clouds. The tasks of robotic object recognition, positioning, and navigation require models that represent such point clouds. It is unclear whether the current methods that perform inference over point clouds are appropriate for these tasks. The current models do not model uncertainty explicitly. This chapter presents models that can be used for point cloud modeling and that represent uncertainty. This (partially) answers research question RQ1. The chapter concludes with recommendations for the development of point cloud inference models. They will be implemented in a new model for line inference in Chapter 3 and line segment inference in Chapter 4.

This chapter describes probability theory, and in particular, measure theory underlying random processes (Section 2.1). Five random processes are described, the Beta process, the Gamma process, the Dirichlet process, the Pitman-Yor process, and the hierarchical Dirichlet process. The random processes are presented as a Poisson process with a Lévy measure, a stick-breaking construction, and a sequential presentation (Section 2.2). These representations give rise to different inference methods. Six inference methods are described: Inverse transform sampling, rejection sampling, approximate Bayesian computation, Gibbs sampling, Metropolis-Hastings, and Split-Merge Markov chain Monte Carlo (Section 2.3). Inference about point clouds in the chapters to follow will use adaptations of the described models and inference methods for which some recommendations are given (Section 2.4).

## 2.1 Probability Theory

Modern probability is based on measure theory (Section 2.1.1). Measure theory will provide the means to formally describe random variables, random processes, and most generally, random measures. A model represented by random measures can be fitted to the data using Bayesian inference (Section 2.1.2). We give three typical examples of Bayesian model compositions, among which an infinite mixture model (Section 2.1.3). A number of processes are described that can be used with (for example as prior distribution) infinite mixture models (Section 2.1.4). We introduce plate notation which visualizes infinite models particularly well (Section 2.1.5). We investigate completely random measures and Lévy measures (Section 2.1.6), exchangeability (Section 2.1.7), and stick-breaking processes (Section 2.1.8), which will form the basis of the processes defined in Section 2.2.

### 2.1.1 Measure Theory

A random variable is a *function* that assigns values to a *set* of possible outcomes. The formal definition requires concepts such as “measurable function” and “probability space” from *measure theory* (Feller, 1950). Measure theory is used to generalize the notion of a random variable to that of a “random process”.

Informally, a measure generalizes the notion of size of Euclidean objects to sets and subsets. The definition of a measure is based on the definition of a  $\sigma$ -algebra. A  $\sigma$ -algebra ascribes a value to a sum of individual disjoint sets, even if they are infinite in number.

---

#### ▼ Definition 2.1 — $\sigma$ -algebra

---

A  $\sigma$ -algebra is a subset  $\Sigma \in 2^X$ , with  $X$  a set and  $2^X$  its powerset, with three requirements:

- $\Sigma$  is non-empty: at least one  $A \in X$  is in  $\Sigma$ ;
  - $\Sigma$  is closed under complementation: if  $A$  in  $\Sigma$ , so is its complement  $A^c$ ;
  - $\Sigma$  is closed under countable unions: if  $A_1, A_2, \dots$  in  $\Sigma$ , so is  $A = A_1 \cup A_2 \cup \dots$
- 

The members of a  $\sigma$ -algebra are called *measurable sets*. Let  $X = \{1, 2, 3, 4\}$  and let us define a  $\sigma$ -algebra  $\Sigma = \{\emptyset, \{1\}, \{4\}, \{2, 3\}, \{1, 4\}, \{1, 2, 3\}, \{2, 3, 4\}, \{1, 2, 3, 4\}\}$ . Here  $\emptyset$  denotes the empty set. The complement of  $A$  is defined with respect to  $X$ :  $A \cup A^c = X$ . An example of closure under complementation: let  $A_1 = \{1\}$ , then  $A_1^c = \{2, 3, 4\}$  and  $A_1^c$  is indeed a member of  $\Sigma$ :  $A_1^c \in \Sigma$ . An example of closure under countable unions: let  $A_1 = \{1\}$  and  $A_2 = \{2, 3\}$ , then  $A_1 \cup A_2 = \{1, 2, 3\}$  and  $A_1 \cup A_2 \in \Sigma$ .

---

#### ▼ Definition 2.2 — *generated* $\sigma$ -algebra

---

A **generated  $\sigma$ -algebra**, with  $X$  a set and  $B \in 2^X$ , is the smallest  $\sigma$ -algebra  $\sigma(B)$  that contains all sets of  $B$ .

---

Let  $X = \{1, 2, 3, 4\}$  and  $B = \{\{1\}, \{2, 3\}\}$ , then the generated  $\sigma$ -algebra is the set  $\sigma(B) = \{\emptyset, \{1\}, \{2, 3\}, \{1, 4\}, \{2, 3, 4\}, \{1, 2, 3, 4\}\}$ . Here the sets in  $B$  are completed to the sets in  $\sigma(B)$  by obeying the requirements of a  $\sigma$ -algebra of closure under complementation and countable unions by addition (e.g.,  $\{1, 4\}$  is added due to closure under completion with respect to  $\{2, 3\}$ ).

The notion of a  $\sigma$ -algebra (Fremlin, 2000) can be applied to solve the so-called Banach-Tarski paradox (Banach and Tarski, 1924). This paradox describes how a unit-ball in  $\mathbf{R}^3$  can be partitioned into a finite number of disjoint infinite sets (scattering of points) and then can be reassembled into two unit-balls again. This violates the intuitive notion of preservation of volume. If the measure  $\mu$  of the union of two disjoint sets is equal to the sum of the measures of the two sets, this is called *finite additivity*:  $\mu(\bigcup_{i=1}^N A_i) = \sum_{i=1}^N \mu(A_i)$ . In probability theory  $\sigma$ -additivity extends this to infinite disjoint sets:  $\mu(\bigcup_{i=1}^{\infty} A_i) = \sum_{i=1}^{\infty} \mu(A_i)$ . Measure theory solves the Banach-Tarski paradox by only assigning a measure to subsets that are measurable sets (Tao, 2011).

A *measure* assigns values to measurable sets (as stated before, measurable sets are members or subsets of  $\Sigma$ ).

### ▼ Definition 2.3 — *measure*

A **measure**  $\mu$  is a function from  $\Sigma$  to  $[-\infty, +\infty]$ , with three requirements:

- $\mu$  is non-negative:  $\mu(A) \geq 0$  for  $\forall A \in \Sigma$ ;
- $\mu$  has a null empty set:  $\mu(\emptyset) = 0$ ;
- $\mu$  is  $\sigma$ -additive:  $\mu(\bigcup_{i \in I_{\Sigma}} A_i) = \sum_{i \in I_{\Sigma}} \mu(A_i)$  for  $A_i$  disjoint.

The first statement defines that a measure  $\mu$  only assigns non-negative values to sets in  $\Sigma$ . The second statement equals the measure of the empty set  $\emptyset$  to 0. The third statement defines that  $\sigma$ -additivity is required. For any two sets in  $\Sigma$  the measure of the union of the sets equals the sum of the measures of the individual sets. Here  $I_{\Sigma}$  defines an index over sets in  $\Sigma$ .

Informally, a measure relates the concepts of *sets* and *subsets* to notions of size. A measure can be seen as a *monotonically* increasing function. Let the set  $A$  in  $X$  be the interval  $[0, 1)$ , an uncountable (infinite) set of real numbers. Define the  $\sigma$ -algebra  $\{\emptyset, A\}$ . The empty set has measure 0, the set  $A$  has measure 1. Let us define the  $\sigma$ -algebra  $\{\emptyset, A_{0,0.5}, A_{0.5,1}, A\}$ . The set  $A_{0,0.5}$  corresponds to the interval  $[0, 0.5)$  and  $A_{0.5,1}$  to  $[0.5, 1)$ . Both sets are assigned measure 0.5 and their union has measure 1. This examples shows that with  $\sigma$ -additive unions, measures can be assigned to sets that are uncountable.

A *measurable space*  $(X, \Sigma)$  is defined as a pair.

---

**▼ Definition 2.4 — measurable space**

---

A **measurable space**  $(X, \Sigma)$  is a pair with:

- $X$  a set;
  - $\Sigma$  a  $\sigma$ -algebra over  $X$ .
- 

A *measure space*  $(X, \Sigma, \mu)$  is defined as a triple.

---

**▼ Definition 2.5 — measure space**

---

A **measure space**  $(X, \Sigma, \mu)$  is a triple with:

- $X$  a set;
  - $\Sigma$  a  $\sigma$ -algebra over  $X$ ;
  - $\mu$  a measure from  $\Sigma$  to  $[-\infty, \infty]$ .
- 

A finite measure  $\mu$  assigns a finite real number to all  $A$ .

---

**▼ Definition 2.6 — finite measure**

---

A **finite measure**  $\mu$  is a measure from  $\Sigma$  to  $[0, \infty)$ :

- $\mu$  is non-negative:  $\mu(A) \geq 0$  for  $\forall A \in \Sigma$ ;
  - $\mu$  has a null empty set:  $\mu(\emptyset) = 0$ ;
  - $\mu$  is  $\sigma$ -additive:  $\mu(\bigcup_{i \in I_\Sigma} A_i) = \sum_{i \in I_\Sigma} \mu(A_i)$  for  $A_i$  disjoint;
  - $\mu$  for the whole sample space,  $X$ , is finite:  $\mu(X) = N$ .
- 

A  $\sigma$ -finite measure allows  $A$  to be a countable union of sets with finite measure.

---

**▼ Definition 2.7 —  $\sigma$ -finite measure**

---

A  **$\sigma$ -finite measure**  $\mu$  is a finite measure with:

- $X$  is a countable union of sets with finite measures.
- 

We will now define five measures: (A) the *probability measure* (Definition 2.8), (B) the *counting measure* (Definition 2.10), (C) the *Borel measure* (Definition 2.12), (D) the *Lebesgue measure* (Definition 2.17), and (E) the *random measure* (Definition 2.18). These measures are important because they are fundamental to different branches of mathematics. In probability theory a  $\sigma$ -algebra is interpreted as a collection of events to which probabilities are assigned. Counting measures play a fundamental role in discrete probability distributions. In integration theory a  $\sigma$ -algebra corresponding to the Borel and Lebesgue measures are relevant for integration in the Euclidean space  $\mathcal{R}^n$ . In statistics a  $\sigma$ -algebra formally defines a sufficient statistics and generalizes random variables to random functions and measures.

### 439 A: Probability measure

440 A *probability measure*,  $\mathbb{P}$ , is a finite measure that assigns non-negative values  $\mathbb{P}$ , called prob-  
 441 abilities, to sets  $A$ , called events (see Definition 2.8).

#### 442 ▼ Definition 2.8 — probability measure

443  
 444 A **probability measure**  $\mathbb{P}$  is a measure  $\mu$  with:

- 445 ○  $\mathbb{P}$  is non-negative:  $\mathbb{P}(A) \geq 0$  for  $\forall A \in \Sigma$ ;
- 446 ○  $\mathbb{P}$  has a null empty set:  $\mathbb{P}(\emptyset) = 0$ ;
- 447 ○  $\mathbb{P}$  is  $\sigma$ -additive:  $\mathbb{P}(\bigcup_{i \in I_\Sigma} A_i) = \sum_{i \in I_\Sigma} \mu(A_i)$  for  $A_i$  disjoint;
- 448 ○  $\mathbb{P}$  for the whole sample space,  $X$ , is unity:  $\mathbb{P}(X) = 1$ .

450 The four requirements are called the Kolmogorov axioms (Kolmogorov, 1933). The prob-  
 451 ability measure is an actual *measure*. It therefore obeys the three requirements: (1) non-  
 452 negativity for any set, (2) the existence of a null empty set, and (3)  $\sigma$ -additivity. Here we  
 453 note that a *probability* measure compared to a general measure obeys a fourth requirement,  
 454 namely the restriction of the measure for the whole space  $X$  to 1. This can be seen as some  
 455 kind of normalization. It influences how two probability measures have to be summed to  
 456 become again a probability measure.

457 In Figure 2.1 the probability measure is visualized as a mapping from the probability space  
 458 to the unit interval  $[0, 1]$ .

**Figure 2.1:** A probability measure  $\mathbb{P}$  mapping the probability space for 3 events to the unit interval. Left: a turning wheel representing three possible outcomes of which the third is twice as likely as the other two outcomes. Right: a probability measure  $\mathbb{P}$  assigned to each outcome. The empty set,  $A = \emptyset$ , has probability measure 0. The set of encountering either 1 or 2,  $B = \{1, 2\}$ , has probability measure 0.5. Taken from Wikipedia.

459 A *probability space*  $(X, \Sigma, \mathbb{P})$  is a measure space  $(X, \Sigma, \mu)$  with the probability measure  $\mathbb{P}$  as  
 460 its measure  $\mu$ .

---

▼ Definition 2.9 — *probability space*

---

A **probability space**  $(X, \Sigma, \mathbb{P})$  is a triple with:

- $X$  a set;
  - $\Sigma$  a  $\sigma$ -algebra over  $X$ ;
  - $\mathbb{P}$  a probability measure from  $\Sigma$  to  $[0, 1]$ .
- 

The triple for the probability space  $(X, \Sigma, \mathbb{P})$  is also written as  $(\Omega, \mathbb{F}, \mathbb{P})$ . The space  $X$  is the event space  $\Omega$ , the set of *elementary outcomes*. The  $\sigma$ -algebra over subsets of  $\Omega$  is denoted by  $\mathbb{F}$ . The probability measure  $\mathbb{P}$  assigns a value on the unit interval  $[0, 1]$  to every event in  $\mathbb{F}$ .

## B: Counting measure

The *counting measure* forms the basis for the definition of discrete probabilities (Schilling, 2005).

---

▼ Definition 2.10 — *counting measure*

---

A **counting measure**  $\nu$  on a space  $X$  is a measure  $\mu$  with:

- $\nu$  is non-negative and integer-valued for  $\forall A \in \Sigma$ ;
  - $\nu < \infty$  for  $\forall A \in \Sigma$  if  $A$  bounded (of finite size);
  - $\nu = \infty$  if  $\exists A \in \Sigma$  with  $A$  unbounded (infinite).
- 

A counting measure is a measure that is integer-valued. Every set  $A$  has a measure that is a positive integer or zero. The set  $A$  is unbounded if and only if its counting measure is infinite.

## C: Borel measure

The *Borel  $\sigma$ -algebra* defines a  $\sigma$ -algebra for the real line  $\mathbb{R}$ .

---

▼ Definition 2.11 — *Borel  $\sigma$ -algebra*

---

A **Borel  $\sigma$ -algebra**  $\mathbb{B}_\sigma$  on  $\mathbb{R}$  is the smallest  $\sigma$ -algebra that contains all open subsets of  $\mathbb{R}$ :

- $\mathbb{B} = \Sigma(U)$  with  $U = U \subseteq \mathbb{R}$ :  $U$  is open.
-

493 The Borel  $\sigma$ -algebra contains all open subsets of  $\mathbb{R}$ . The property of closure under comple-  
 494 mentation of a  $\sigma$ -algebra means that it also contains the closed subsets of  $\mathbb{R}$ . If  $A = (0, 1)$ ,  
 495 then  $A^c = \{[-\infty, 0], [1, \infty]\}$ .

496 A Borel measure assigns values to subsets of  $\mathbb{B}_\sigma$ .

497 **▼ Definition 2.12 — Borel measure**

498 

---

499 A Borel measure  $\mu$  is a function from  $\Sigma = \mathbb{B}_\sigma$  to  $[-\infty, +\infty]$ , with the three measure  
 500 requirements:

- 501   ◦  $\mu$  is non-negative:  $\mu(A) \geq 0$  for  $\forall A \in \Sigma$ ;
  - 502   ◦  $\mu$  has a null empty set:  $\mu(\emptyset) = 0$ ;
  - 503   ◦  $\mu$  is  $\sigma$ -additive:  $\mu(\bigcup_{i \in I_\Sigma} A_i) = \sum_{i \in I_\Sigma} \mu(A_i)$  for  $A_i$  disjoint.
- 504 

---

505 The Borel space is a measurable space with a Borel  $\sigma$ -algebra rather than a general  $\sigma$ -  
 506 algebra.

507 **▼ Definition 2.13 — Borel space**

508 

---

509 A Borel space  $(X, \mathbb{B}_\sigma)$  is a pair with:

- 510   ◦  $X$  a set;
  - 511   ◦  $\mathbb{B}_\sigma$  a Borel  $\sigma$ -algebra over  $X$ .
- 512 

---

513 A complete measure space is a measure space in which every subset of every null set is mea-  
 514 surable.

515 **▼ Definition 2.14 — complete measure space**

516 

---

517 A complete measure space  $(X, \Sigma, \mu)$ :

- 518   ◦  $S \subseteq N \in \Sigma$  and  $\mu(N) = 0 \Rightarrow S \in \Sigma$ .
- 519 

---

520 The Borel space is not a complete measure space. There are sets in the Borel  $\sigma$ -algebra that  
 521 are of measure zero and that contain subsets that are undefined.

522 **D: Lebesgue measure**

523 The Lebesgue measure defines a size to subsets of  $\mathbb{R}^n$  that completes the Borel measure  
 524 (Lebesgue, 1902). It makes use of the notion of an outer measure.

525 **▼ Definition 2.15 — outer measure**

526 

---

527 An outer measure  $\phi$  on a space  $\mathbb{R}$  is a measure  $\mu$  with:

- 528      ◦  $\phi$  is non-negative and real-valued for  $\forall A \in \Sigma$ ;
  - 529      ◦  $\phi$  has a null empty set:  $\phi(\emptyset) = 0$ ;
  - 530      ◦  $\phi$  is  $\sigma$ -subadditive:  $\phi(\bigcup_{i \in I_\Sigma} A_i) < \sum_{i \in I_\Sigma} \mu(A_i)$  for  $\forall A_i$ ;
  - 531      ◦  $\phi$  is monotone:  $A \subseteq B$  implies  $\phi(A) \leq \phi(B)$ ;
  - 532      ◦  $\phi$  is translation-invariant:  $\phi(A + x) = \phi(A)$  for  $\forall A \in \Sigma$  and  $\forall x \in \mathbb{R}$ .
  - 533
- 

534 An outer measure relaxes  $\sigma$ -additivity of disjoint sets of  $X$  to  $\sigma$ -subadditivity for any se-  
 535 quence of sets. Intuitively, the outer measure of a set is an upper bound on the size of a  
 536 set.

537      ▼ **Definition 2.16 — Lebesgue outer measure**

---

538  
 539 A **Lebesgue outer measure**  $\lambda$  on a space  $\mathbb{R}^n$  is an outer measure  $\phi$  with:

- 540      ◦  $\lambda(A) = \inf \left\{ \sum_{k=1}^{\infty} l(I_k) : (I_k)_{k \in \mathbb{N}} \text{ is a sequence of open intervals with } A \subseteq \bigcup_{k=1}^{\infty} I_k \right\}$ .
  - 541
- 

542 Here  $A \subseteq \mathbb{R}$  is a subset of the real line. The Lebesgue outer measure  $\lambda$  is the infimum (greatest  
 543 lower bound) of the sum of the lengths  $l(I) = b - a$  of the intervals  $I = [a, b]$ .

544 The *Lebesgue measure* is defined through the Lebesgue outer measure.

545      ▼ **Definition 2.17 — Lebesgue measure**

---

546  
 547 A **Lebesgue measure**  $m$  on a space  $\mathbb{R}^n$  is a Lebesgue outer measure  $\lambda$  with:

- 548      ◦  $m(B) = \lambda(B \cup A) + \lambda(B \cup A^c)$ .
  - 549
- 

550      **E: Random measure and random process**

551 A measurable function is defined between two measurable spaces.

552      ▼ **Definition 2.18 — measurable function**

---

553  
 554 A **measurable function**  $f : X \rightarrow Y$  fulfills:

- 555      ◦  $f^{-1}(E) \in \Sigma$       for       $\forall E \in T$ ,

556 with both  $(X, \Sigma)$  and  $(Y, T)$  measurable spaces.

---

558      A measurable function *preserves the structure* of the corresponding measurable spaces  
 (captured through the  $\sigma$ -algebras).

559 A random variable is a measurable function between two measurable spaces, with as domain  
 560 a measurable space that is a probability space.

---

▼ **Definition 2.19 — general random variable**

---

A  $(X, \Sigma)$ -valued random variable  $X$  is a measurable function from probability space  $(\Omega, \mathbb{F}, \mathbb{P})$  to measurable space  $(X, \Sigma)$ .

---

A random variable is a  $(X, \Sigma)$ -valued random variable with a choice for the codomain and  $\sigma$ -algebra (see Definition 2.20).

---

▼ **Definition 2.20 — random variable**

---

A random variable  $X$  is a measurable function from probability space  $(\Omega, \mathbb{F}, \mathbb{P})$  to the real line with the Borel  $\sigma$ -algebra  $(\mathbb{R}, \mathbb{B}_{\mathbb{R}})$ .

---

The codomain is the real line  $\mathbb{R}$  and the Borel  $\sigma$ -algebra.

Random variables can be generalized to complex random variables or random elements of any type. A *complex random variable* is a measurable function from  $\Omega$  to  $\mathbb{C}$ . A *random elephant* is a measurable function from  $\Omega$  to a suitable space of elephants (Kingman, 1993).

---

▼ **Definition 2.21 — random measure**

---

A random measure is a function  $\xi : \Omega \times X \rightarrow [0, +\infty]$  from probability space  $(\Omega, \mathbb{F}, \mathbb{P})$  to measurable space  $(X, \Sigma)$  such that  $\xi(\cdot, X)$  is a random variable on  $(\Omega, \mathbb{F}, \mathbb{P})$  and  $\xi(\omega, \cdot)$  is a measure on  $\Sigma$ .

---

We have encountered a random variable, and a probability measure  $\mathbb{P}$  on the original probability space. Now, one might wonder whether probabilities are logically assigned to elements on the measurable space that is the codomain of this random variable. Why does it map to a measurable space and not a measure space actually? This is because (through the  $\sigma$ -algebras of both spaces, or more precisely the random variable itself) the probability measure is *induced* on the target space. This is known as a *probability distribution*:

---

▼ **Definition 2.22 — probability distribution**

---

Given a random variable  $X$  from  $(\Omega, \mathbb{F}, \mathbb{P})$  to  $(\mathbb{R}, \mathbb{B}_{\sigma})$ , the **probability distribution**  $\mu$  is the induced probability measure:  $\mu(B) = \mathbb{P}(X^{-1}(B))$  for all Borel sets  $B \in \mathbb{B}_{\sigma}$ .

---

The measurable function  $X$  is inverted:  $X^{-1}(\cdot)$ . The measure  $\mu$  exists on  $(\mathbb{R}, \mathbb{B}_{\sigma})$  just as  $\mathbb{P}$  exists on  $(\Omega, \mathbb{F})$ . The notation for the measure  $\mu$  does not include the original probability space or  $\sigma$ -algebra. The complete notation for the probability distribution  $\mu$  can be written as a function  $f$  of  $X$ :

$$f_X(x) = f_{X,(\Omega,\mathbb{F},\mathbb{P}),(\mathbb{R},\mathbb{B}_{\sigma})}(x). \quad (2.1)$$

At the left  $X$  denotes the random variable,  $x \in \Omega$  are the (elementary) outcomes on the sample space  $\Omega$ . At the right the complete notation adds  $\mathbb{F}, \mathbb{P}$  and  $\mathbb{R}, \mathbb{B}_\sigma$ . The shorthand notation at the left will be used to indicate the real line with a Borel  $\sigma$ -algebra as codomain.

A random variable  $X$  is *distributed* as  $f_X(x)$ , notation:

$$X \sim f_X(x). \quad (2.2)$$

A *random process* is an *ordered* set of random variables. The set can be a sequence of random variables in a time series. It can be a series of steps in the spatial domain, called a random field.

---

▼ **Definition 2.23 — random process**

---

A **random process**  $X$  is a collection  $\{X_t : t \in T\}$  with  $X_t$  an  $(S, \Sigma)$ -valued random variable on  $\Omega$  and  $(\Omega, \mathbb{F}, \mathbb{P})$  a probability space,  $(S, \Sigma)$  a measurable space, and  $T$  a totally ordered set.

---

A random process is a probability distribution with a domain that is a set of probability distributions. A random process is a distribution over distributions, a hierarchy over distribution.

### 2.1.2 Bayesian Inference

Let  $x$  be a  $(S, \Sigma_S, \mu_S)$ -valued random variable<sup>1</sup>,  $y$  a  $(T, \Sigma_T, \mu_T)$ -valued random variable, then we can construct  $z$ , a  $(C, \Sigma_C, \mu_C)$ -valued random variable with the latter being a subset of the product set of  $x$  and  $y$ :  $C \in S \otimes T$ .

---

▼ **Definition 2.24 — product space**

---

A **product space**  $(S \otimes T, \Sigma_{S \otimes T})$  has  $\sigma$ -algebra  $\Sigma_{S \otimes T} = \sigma(F \otimes G : F \in \Sigma_S, G \in \Sigma_T)$  with  $(S, \Sigma_S, \mu_S)$  and  $(T, \Sigma_T, \mu_T)$  two  $\sigma$ -finite measure spaces.

---

---

▼ **Definition 2.25 — product measure**

---

A **product measure**  $\mu_{S \otimes T}$  is a measure  $\mu_{S \otimes T}(F \otimes G) = \mu_S(F) \otimes \mu_T(G)$  with  $(S, \Sigma_S, \mu_S)$  and  $(T, \Sigma_T, \mu_T)$  two  $\sigma$ -finite measure spaces.

---

The **joint probability distribution**  $P_C$  is a probability measure on the product  $\sigma$ -algebra  $\Sigma_C$  with  $C \in S \otimes T$ . As function of the random variables  $x$  and  $y$  the joint probability distribution is written as  $_{X,Y}(x, y)$ ,  $f(x, y)$ , or  $p(x, y)$ .

A  $\sigma$ -algebra is *independent* in the following sense.

---

<sup>1</sup>The lowercase  $x$  is used instead of  $X$  in the context of probability distributions as in eq. (2.1).

---

▼ **Definition 2.26 — independent  $\sigma$ -algebra**

---

Let  $(\Omega, \mathbb{F}, P)$  be a probability space and  $\mathbb{A}$  and  $\mathbb{B}$  be sub- $\sigma$ -algebras of  $\mathbb{F}$ .  $\mathbb{A}$  and  $\mathbb{B}$  are **independent  $\sigma$ -algebras** if:

- $P(A \cap B) = P(A)P(B) \quad \forall A \in \mathbb{A} \text{ and } B \in \mathbb{B}.$

---

Two random variables  $x$  and  $y$  are independent if and only if the  $\sigma$ -algebras that they generate are independent.

---

▼ **Definition 2.27 — conditional probability distribution**

---

Let  $(\Omega, \mathbb{F}, P)$  be a probability space,  $\mathbb{G} \subseteq \mathbb{F}$  a sub- $\sigma$ -algebra of  $\mathbb{F}$ , and  $X : \Omega \rightarrow \mathbb{R}$  a real-valued random variable ( $\mathbb{F}$ -measurable with respect to the Borel  $\sigma$ -algebra  $\mathbb{B}_\sigma$  on  $\mathbb{R}$ ). There exists a function  $\mu : \mathbb{B}_\sigma \times \Omega \rightarrow \mathbb{R}$  such that  $\mu(\cdot, \omega)$  is a probability measure on  $\mathbb{B}_\sigma$  for each  $\omega \in \Omega$  and  $\mu(H, \cdot) = P(X \in H | \mathbb{G})$  (almost surely) for every  $H \in \mathbb{B}_\sigma$ . For any  $\omega \in \Omega$ , the function  $\mu(\cdot, \omega) : \mathbb{B}_\sigma \rightarrow \mathbb{R}$  is called a **conditional probability distribution** of  $X$  given  $\mathbb{G}$ .

---

Informally, a conditional probability is described with a sub- $\sigma$ -algebra which only presents part of the structure of the full  $\sigma$ -algebra. As function of the random variables  $x$  and  $y$  the conditional probability distribution of  $y$  given  $x$  is written as  $f_{Y|X}(y|x)$ ,  $f(y|x)$ , or  $p(y|x)$ .

The random variables  $x$  and  $\theta$  define a Bayesian model with observations  $x$  and parameters  $\theta$ .

---

▼ **Definition 2.28 — Bayesian model**

---

A **Bayesian model**  $f(x, \theta)$  defines a function between observations  $x$  and parameters  $\theta$  with both  $x$  and  $\theta$  random variables.

---

In a **supervised learning** task both  $x$  and  $\theta$  are known. In an **unsupervised learning** task  $x$  is known, but  $\theta$  is unknown. The random variable  $\theta$  is called a hidden or latent variable. The random variable  $\theta$  can be any random element: a random vector, a random matrix, a random process.

Let the observations  $x$  be a sequence  $x_0, x_1, \dots$ , then the observations  $x_i$  can be distributed *independent and identically*.

---

▼ **Definition 2.29 — independent and identically distributed**

---

A collection of random variables  $x = \{x_0, x_1, \dots\}$  is **independent and identically distributed (i.i.d.)** if:

- the probability distribution  $p(x_i)$  is the same for  $\forall x_i \in x$ ;
  - each  $x_i$  is independent with respect to  $x_j$  with  $i \neq j$ .
-

The observations  $x_i$  can be distributed in an *exchangeable* sequence in which any order is equally likely.

---

▼ **Definition 2.30 — *exchangeable***

---

A sequence of random variables  $x = \{x_0, x_1, \dots\}$  is **exchangeable** if for any finite permutation  $\rho$  of the indices  $0, 1, \dots$ :

- the joint probability distribution of the permuted sequence  $p(x_{\rho(0)}, x_{\rho(1)}, \dots)$  equals that of the original sequence  $p(x_0, x_1, \dots)$ .
- 

The joint probability distribution of i.i.d. observations given parameters can be written as a product:

$$p(x_0, \dots, x_{k-1} | \theta) = \prod_{i=0}^{k-1} p(x_i | \theta). \quad (2.3)$$

---

▼ **Definition 2.31 — *likelihood function***

---

The **likelihood function** is defined as:

$$\mathcal{L}(\theta | x) = p(x | \theta). \quad (2.4)$$

The likelihood of the parameters  $\theta$  given observations  $x$  is the probability of these observations given the parameter values.

The definition of the likelihood function allows us to find an optimal set of parameter values given the observations. The probability  $p(x | \theta)$  can be maximized (Aldrich and Others, 1997).

---

▼ **Definition 2.32 — *maximum likelihood***

---

**Maximum likelihood** is defined as:

$$\theta^* \in \operatorname{argmax}_{\theta} \prod_{i=0}^{k-1} p(x_i | \theta). \quad (2.5)$$

The maximum likelihood method finds the maximum of  $\prod_{i=0}^{k-1} p(x_i | \theta)$  for all possible parameter values  $\theta$ . The maximum in maximum likelihood does not need to be unique (Steel, 1994). The notation makes this explicit by writing  $\theta^*$  as a member (denoted by the  $\in$  symbol) of the outcomes of the argmax operation (and does not use the equal sign).

699 A function  $f(\cdot)$  and the logarithm of a function  $\log f(\cdot)$  have the same maxima. This is due  
 700 to the fact that the logarithm is a monotonic function (a monotonically increasing function).  
 701 The log of a product of logarithms is equal to the sum of the individual logarithms.

702 **▼ Definition 2.33 — *maximum log-likelihood***

703 **Maximum log-likelihood** is defined as:

$$\theta^* \in \operatorname{argmax}_{\theta} \sum_{i=0}^{k-1} \log p(x_i | \theta). \quad (2.6)$$

705

706

707 In the case we have information about the parameters  $\theta$  we can model this with a probability  
 708 distribution.

709 **▼ Definition 2.34 — *prior probability distribution***

710 A **prior probability distribution** defines a probability distribution  $p(\theta)$  to parameters  
 711  $\theta$  without a dependency on the observations  $x$ .  
 712

713

714 Given the definition of a prior probability distribution, we can define *maximum a posteriori*  
 715 estimation.

716 **▼ Definition 2.35 — *maximum a posteriori***

717 **maximum a posteriori** estimation is defined as:

$$\theta^* \in \operatorname{argmax}_{\theta} \sum_{i=0}^{k-1} \log p(x_i | \theta) + \log p(\theta). \quad (2.7)$$

719

720

721 If we are not only interested in the parameter  $\theta^*$  that maximizes  $p(x|\theta)$  and  $p(\theta)$ , but in  
 722 the complete distribution for  $p(\theta)$  we need Bayes' theorem described by Laplace (1820).

723 **▼ Definition 2.36 — *Bayesian inference***

724 **Bayesian inference** using Bayes' theorem is defined as:

$$f(\theta|x) = p(\theta|x) = \frac{\overbrace{p(x|\theta)}^{\text{likelihood}} \overbrace{p(\theta)}^{\text{prior}}}{\underbrace{p(x)}_{\text{normalization constant}}} = \frac{p(x|\theta)p(\theta)}{\int p(x|\theta)p(\theta)d\theta}. \quad (2.8)$$

726

727

Bayes' theorem describes the posterior probability  $p(\theta|x)$  as the likelihood times the prior probability distribution divided by a normalization constant, also called the evidence. The normalization constant is not a function of the parameters  $\theta$ . If a function is known except for the normalization constant, it is indicated by the "proportional to" symbol  $\propto$ .

$$f(\theta|x) \propto p(x|\theta)p(\theta) \quad (2.9)$$

In Bayesian inference  $p(\theta|x)$  is calculated. In contrast, in maximum likelihood and maximum a posteriori only parts of eq. (2.8) are calculated, respectively  $p(x|\theta)$  and  $p(x|\theta)p(\theta)$ . In Section 2.3 inference methods will be described that approximate Bayesian inference. Approximation is required in the case closed-form expressions are not available. If the inference task only requires maximum a posteriori, approximation methods are also available (Daume, 2007), but this is outside of the scope of the current thesis.

There are two supervised learning models, a generative model and a discriminative model. Below we provide their definitions and in Figure 2.2 we give three examples for each model.

---

▼ **Definition 2.37 — generative model**

---

A **generative** model defines the joint probability distribution  $p(x, \theta)$  and uses Bayes rule to define  $p(x|\theta)$ .

---

---

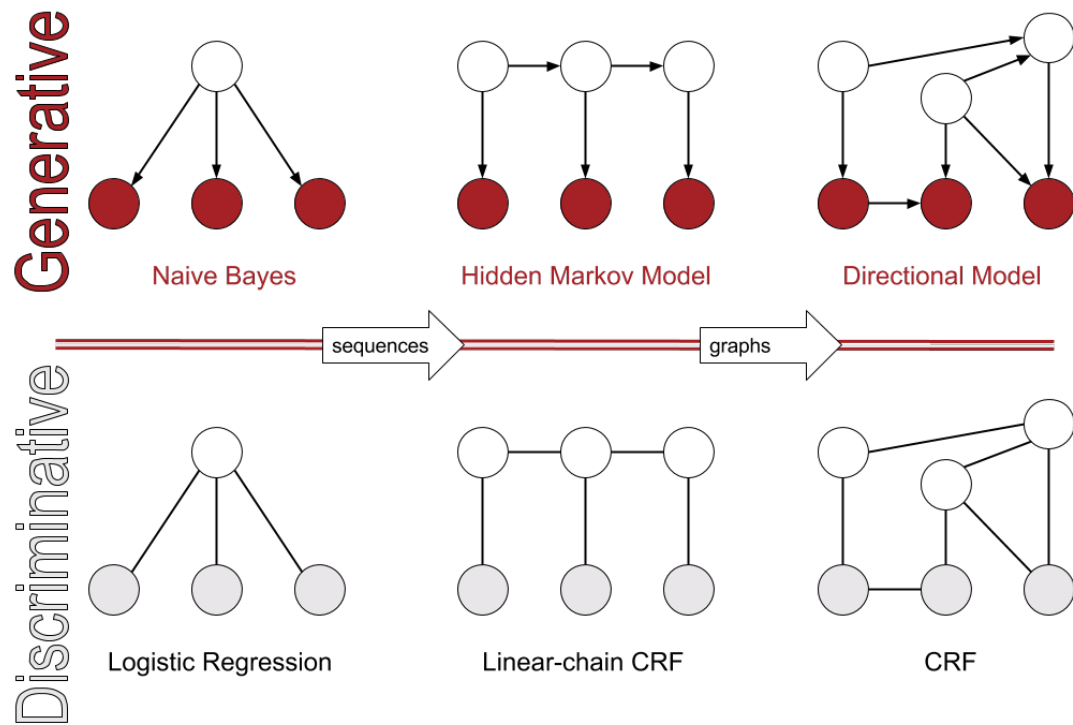

▼ **Definition 2.38 — discriminative model**

---

A **discriminative** model defines the conditional probability distribution  $p(x|\theta)$  directly.

---

Figure 2.2 shows three generative and three discriminative models. They are chosen for their structure; from left to right, in both cases, the structure between the random variables is enriched, first in the form of a sequence structure, then in the form of a graph structure. Figure 2.2 visualizes three generative models: (1) the Naive Bayes Model (Russell et al., 1995), (2) the Hidden Markov Model (Baum and Petrie, 1966), and (3) the Directional Model (Koller and Friedman, 2009). It shows also three discriminative models: (1) Logistic Regression, (2) Linear-chain Conditional Random Fields, and (3) general Conditional Random Fields.

**Figure 2.2:** Generative models: Naive Bayes Model, Hidden Markov Model, and Directional Model. Discriminative models: Logistic Regression, Linear-chain Conditional Random Fields, and general Conditional Random Fields. Figure adapted from Sutton and McCallum (2011).

There is no definitive reason to use a generative model rather than a discriminative model or vice-versa. Here we confine ourselves to two remarks. First, a discriminative model has lower asymptotic error, but a generative model approaches its asymptotic error faster in the case of a Naive Bayes classifier versus Logistic Regression (Jordan, 2002). However, Xue and Titterington (2008) doubt the existence of such precisely defined regimes. According to them the asymptotic error denotes the error with an increasing number of samples. Second, the prior  $p(\theta)$  in the generative model provides a principled way to handle missing information, while the direct modeling of decision boundaries in a discriminative model often leads to better performance in a classification task (Jaakkola et al., 1999). Apart from generative models and discriminative models, there are also hybrid models (Bouchard and Triggs, 2004; Raina et al., 2003; Bosch et al., 2008). In the thesis we will limit ourselves to generative models.

### 2.1.3 Model Composition

A model can be composed out of a set of probability distributions. We list three of such possible compositions. The Naive Bayes model is a *product* of probability distributions with a prior distribution (Definition 2.39). The finite mixture model is a *sum* over a finite number

of probability distributions where each one is weighted (Definition 2.40). The infinite mixture model is a *sum* over an infinite number of probability distributions where each one is weighted (Definition 2.41).

---

▼ **Definition 2.39 — *naive Bayes model***

---

The **naive Bayes model** is a product over a finite number  $k \neq \infty$  of probability distributions  $p(x_i|\theta)$  multiplied by the prior distribution  $p(\theta)$ :

$$p(\theta|x) \propto p(\theta) \prod_{i=0}^{k-1} p(x_i|\theta). \quad (2.10)$$

---

A finite mixture model is a sum over a finite number of probability distributions.

---

▼ **Definition 2.40 — *finite mixture model***

---

A **finite mixture model** is a sum over a finite number  $k \neq \infty$  of probability distributions  $p(x_i)$ , with each distribution weighted by a factor  $w_i$  with  $\sum_i w_i = 1$ .

$$p(x) = \sum_{i=0}^{k-1} w_i p(x_i). \quad (2.11)$$

---

The mixture model is finite in the sense that there are only  $k \neq \infty$  distributions summed up. The weights of the individual distributions  $p(x_i)$  are normalized (sum up to one) such that the weighted sum over the probability distributions is itself a probability distribution.

An infinite mixture model is a sum over an infinite number of probability distributions.

---

▼ **Definition 2.41 — *infinite mixture model***

---

A **infinite mixture model** is a sum over an infinite number of probability distributions  $p(x_i)$ , with each distribution weighted by a factor  $w_i$  with  $\sum_i w_i = 1$ .

$$p(x) = \sum_{i=0}^{\infty} w_i p(x_i). \quad (2.12)$$

---

The infinite mixture model is a sum over an infinite number of probability distributions with weights that sum up to one. In this way it assigns a finite value to a countably infinite set of functions. In the thesis we will encounter infinite mixture models in Chapters 3 and 4.

A mixture model relates one latent cause (cluster) to each data point. A factorial model or feature allocation model assigns multiple factors to a data point.

---

**▼ Definition 2.42 — *feature model***

---

A **feature model** is a sum over a finite number  $k \neq \infty$  of sets of probability distributions  $p(x_{C_i})$ .

$$p(x) = \sum_{i=0}^{n-1} \sum_{j=0}^{C_i} p(x_j). \quad (2.13)$$

---

A counting model allows each feature to occur multiple times.

---

**▼ Definition 2.43 — *counting model***

---

A **counting model** is a sum over a finite number  $k \neq \infty$  of sets of probability distributions  $p(x_{C_i})$  with each feature occurring a number  $c_j$  of times.

$$p(x) = \sum_{i=0}^{n-1} \sum_{j=0}^{C_i} c_j p(x_j). \quad (2.14)$$

---

### 2.1.4 General Random Elements

In section 2.1.1 random elements were described in general. Random elements can vary from random vectors, random distributions, random clusters (partitions), to random trees. Table 2.1 describes the random elements and the corresponding examples of random processes in the literature. Below we mention them with the appropriate references.

The Gaussian Process (Rasmussen and Williams, 2006) describes a distribution on functions. The Beta Process (Hjort, 1990), the Gamma Process (Ferguson, 1974), the Dirichlet Process and the Polya Tree (Ferguson, 1973) describe a distribution on distributions. The Chinese Restaurant Process (Aldous, 1985) and Pitman-Yor Process (Pitman and Yor, 1997) describe a distribution on partitions (in the form of cluster assignments). The Stick-breaking Process describes a distribution on partition sizes (with no information on assignments themselves). The Dirichlet Diffusion Tree (Neal, 2001) and Kingman's coalescence (Kingman, 1965) describe a distribution on hierarchical partitions. The Indian Buffet Process (Ghahramani and Griffiths, 2005) describes a distribution over sparse binary matrices. The Gamma-Poisson Process (Titsias, 2008) describes a distribution over integer-valued matrices. The Mondrian Process (Roy and Teh, 2009) describes a distribution over kd-trees.

### 2.1.5 Plate Notation

Random processes and mixture models are visually represented by a method called *plate notation* (Koller and Friedman, 2009). Sets of variables are represented in a plate, a rectangular region (see Figure 2.3).

**Table 2.1:** A list of seven mathematical structures and for each of these structures one or more random processes that can generate the structure. For example, a distribution on distributions can be generated by a Beta Process, Gamma Process, Dirichlet Process, or a Polya Tree.

Structure	Example
Distribution on functions	Gaussian Process
Distribution on distributions	Beta Process Gamma Process Dirichlet Process Polya Tree
Distribution on partition assignments	Chinese Restaurant Process Pitman-Yor Process
Distribution on partition sizes	Stick-breaking Process
Distribution on hierarchical partitions	Dirichlet Diffusion Tree Kingman’s coalescence
Distribution on sparse binary matrices	Indian Buffet Process
Distribution on integer-valued matrices	Gamma-Poisson Process
Distribution on kd-trees	Mondrian Process

**Figure 2.3:** Top: graphical model of a Naive Bayes, hidden Markov model, and Gaussian process. Bottom: corresponding plate notation of the Naive Bayes, hidden Markov model, and Gaussian process. Observed variables are denoted by a circle that is shaded.

838 Plate notation is a representation that does not preserve all dependencies between variables.

For example, the dependencies between the states in the Hidden Markov Model (e.g., between  $\theta_0$  and  $\theta_1$ ) are not represented.

### 2.1.6 Completely Random Measure and Lévy Measure

Some random process are mathematically represented by a completely random measure (Kingman, 1967), which is defined as follows.

#### ▼ Definition 2.44 — *completely random measure*

A **completely random measure** is a random measure  $\mu : \Omega \times X \rightarrow [0, +\infty]$  from probability space  $(\Omega, \mathbb{F}, \mathbb{P})$  to measurable space  $(X, \Sigma)$  with

- for any collection of disjoint sets  $A_1, \dots, A_k \in \Sigma$  and  $A_i \cap A_j = \emptyset$  for  $i \neq j$  a mutual independency between  $\mu(A_1), \dots, \mu(A_k)$ .

Kingman (1967) shows that a completely random measure can be decomposed into three components:

1. a deterministic function;
2. a countable set of non-negative random masses at deterministic locations;
3. a countable set of non-negative random masses at random locations.

The first component is a deterministic function. The second component has non-negative random masses, also called atoms, on deterministic locations. The third component is the one of interest. It has a set of random masses (atoms) that can be represented as a Poisson random measure on  $\mathbb{R}^+ \otimes X$  with mean measure  $\nu$  which is known as the Lévy intensity measure (Favaro et al., 2013).

**Table 2.2:** Lévy measure of the Beta Process (Wang and Carin, 2012), Gamma Process (Knowles et al., 2014), the Dirichlet Process (Lijoi and Prünster, 2010) (indirectly through  $F = 1 - e^{-\nu}$ ).

Random Process	Lévy measure
Beta Process	$\nu(da, dw) = H(da)\alpha w^{-1}(1-w)^{\alpha-1}dw$
Gamma Process	$\nu(da, dw) = H(da)w^{-1}e^{-\alpha w}dw$
Dirichlet Process	$\nu(da, dw) = H(da)e^{-w\alpha(x, \infty)}(1-e^{-w})^{-1}dw$

For Lévy measure decompositions of other processes such as the Indian buffet process, we refer to Wang and Carin (2012).

### 2.1.7 Exchangeability

Here we recall Definition 2.30 for exchangeable sequences. De Finetti's theorem states that there is parameter  $\theta$  such that the data  $x_i$  is conditionally independent given this parameter for exchangeable sequences (cf. De Finetti, 1937).

#### ▼ Definition 2.45 — De Finetti's theorem

A sequence  $\{x_0, x_1, \dots\}$  of  $(X, \Sigma_X)$ -valued random variables is an infinitely exchangeable sequence if and only if there exist a measure  $\mu(d\theta)$  on  $\theta$  such that

$$p(x_0, \dots, x_{k-1}) = \int_{\Sigma_X(X)} \prod_{i=0}^{k-1} p(x_i|\theta) \mu(d\theta) \quad \forall k \geq 1. \quad (2.15)$$

In words, de Finetti's theorem states that if we have *exchangeable* data, we have a parameter  $\theta$ , a likelihood  $p(x|\theta)$ , and some measure  $\mu$  on  $\theta$ , such that the data  $(x_0, \dots, x_{k-1})$  is *conditionally independent*. Hence, although the data is not i.i.d., there are underlying, unobservable, quantities that are i.i.d. and exchangeable sequences are mixtures of these quantities. The theorem proves that if the observations are exchangeable, they must be a random sample from some model and there must exist a prior probability distribution over the parameters of that model, hence requiring a Bayesian approach.

The theorem is not limited to exchangeable *sequences*. In contrast, there are similar theorems for other exchangeable objects (Orbanz and Roy, 2015). Five examples (see Table 2.3) of exchangeable structures that have a theorem that describes an underlying measure that can be sampled i.i.d. are: (1) exchangeable sequences (de Finetti, 1930), (2) increments (Bühlmann, 1960), (3) partitions (Kingman, 1978), (4) arrays (Aldous, 1981), and (5) Markov chains (Diaconis and Freedman, 1980).

**Table 2.3:** Five exchangeable structures and their theorems.

Mathematical Object	Theorem
Exchangeable Sequence	de Finetti
Exchangeable Increment	Bühlmann
Exchangeable Partition	Kingman
Exchangeable Array	Aldous-Hoover
Exchangeable Markov Chain	Diaconis-Freedman

### 2.1.8 Stick-breaking Representation

Now we introduce the *stick-breaking representation* by Freedman and Diaconis (1983), also known as the residual allocation model (Sawyer and Hartl, 1985; Hoppe, 1986).

▼ **Definition 2.46 — stick-breaking**

An infinite sequence of random variables  $\phi = \{\phi_0, \phi_1, \dots\}$  has a **stick-breaking representation** with parameters  $\alpha$  and  $\beta$  denoted by  $\phi \sim GEM(\alpha, \beta)$ .

$$w_k \stackrel{i.i.d.}{\sim} \text{Beta}(1 - \beta, \alpha + k\beta) \quad k = 1, \dots, K \quad (2.16)$$

$$\phi_k = w_k \prod_{i=1}^{k-1} (1 - w_i) \quad (2.17)$$

889

890

891 The stick-breaking process samples repeatedly from a  $\text{Beta}(1 - \beta, \alpha + k\beta)$  distribution. The  
 892 result of the process is a vector of  $k$  weights  $\phi_k$ . The abbreviation *GEM* stands for Griffiths,  
 893 Engen, and McCloskey (Ewens, 1990; Ethier, 1990). There is also a variant of GEM with a  
 894 single parameter  $\alpha$  which can be obtained by setting  $\beta = 0$ . In that case  $w_k$  are drawn from  
 895 a  $\text{Beta}(1, \alpha)$  distribution.

**Figure 2.4:** The stick-breaking representation. Left: at the first row, the stick is broken at  $x_0$ , at the next rows the remaining part of the stick is broken  $x_i$  with  $i > 0$ . Only six iterations are shown. Right: samples of a stick-breaking process. The first row shows the stick ratios from the stick-breaking representation at the left. The next rows show other samples from the same process.

896 Figure 2.4 visualizes the stick-breaking process. A stick of fixed length 1 gets broken at a  
 897 position  $w_0$  sampled from a Beta distribution. The remainder of the stick is broken again at  
 898 position  $w_1(1 - w_0)$ . This process continues for an infinite number of times. In this manner  
 899 generates a stick-breaking process a sequence of non-negative values that sum up to one.  
 900 The stick-breaking representation can on itself give rise to more sophisticated stochastic  
 901 processes (Dunson et al., 2012). Computationally it can also fulfill a useful rule. Namely,  
 902 it is possible to approximate a distribution over partitions by truncating a stick-breaking  
 903 process. The stick-breaking is then only performed a limited number of times (Kurihara  
 904 et al., 2007).

905 In Section 2.2.1 the relevance of the stick-breaking process for the Dirichlet process will be  
 906 shown. In that case the values generated by the stick-breaking process represent the weights  
 907 of the partitions induced by the Dirichlet Process.

## 908 2.2 Five Random Processes

909 In this section we investigate five random processes. The Dirichlet process (Section 2.2.1),  
 910 the Beta process (Section 2.2.2), the Gamma process (Section 2.2.3), the Pitman-Yor process  
 911 (Section 2.2.4), and the hierarchical Dirichlet process (Section 2.2.5). We compare the  
 912 random processes in Section 2.2.6.

### 913 2.2.1 Dirichlet Process

914 The Dirichlet process is presented as a measure (Section A), is shown to have a sequential  
 915 representation in the form of the Chinese restaurant process (Section B), and a stick-breaking  
 916 representation (Section C).

#### 917 A: Dirichlet Process as a Measure

918 The Dirichlet process (DP) is a distribution over distributions (Ferguson, 1973).

#### ▼ Definition 2.47 — Dirichlet process

A Dirichlet process  $DP$  over a set  $S$  can be used to draw sample paths  $X$ :

$$X \sim DP(\alpha, H)$$

with  $\alpha$  the dispersion parameter and  $H$  a measure on  $S$  and for which any measurable  
 partition  $\{B_0, \dots, B_{n-1}\} \in S$  is drawn from a Dirichlet distribution:

$$(X(B_0), \dots, X(B_{n-1})) \sim \text{Dirichlet}(\alpha H(B_0), \dots, \alpha H(B_{n-1}))$$

919

920

921 The Lévy intensity of the Dirichlet process is complicated, because it is a so-called normalized  
 922 process, see Regazzini et al. (2003).

923 The Dirichlet process can be used as a prior for a mixture model (Definition 2.41). This is  
 924 visualized in (Figure 2.5).

	$\theta_0$	$\theta_1$	$\theta_2$	$\theta_3$	$\theta_4$	$\theta_5$	$\theta_6$	$\theta_7$	$\theta_8$	$\theta_9$	sum
data 0	0	0	1	0	0	0	0	0	0	...	1
data 1	1	0	0	0	0	0	0	0	0	...	1
data 2	1	0	0	0	0	0	0	0	0	...	1
data 3	0	1	0	0	0	0	0	0	0	...	1
data 4	1	0	0	0	0	0	0	0	0	...	1
data 5	0	1	0	0	0	0	0	0	0	...	1
data 6	0	0	0	0	1	0	0	0	0	...	1

**Figure 2.5:** Matrix representation of a mixture model. At the horizontal axis the latent variables (potentially infinite clusters). At the vertical axis the data items. The rows sum up to one. A data item is only assigned to one cluster.

## 925 B: Chinese Restaurant Process

926 De Finetti's theorem (Definition 2.45) can be used to establish the existence of an infinitely  
 927 exchangeable sequence. In the particular case of the Dirichlet process the sequence is an  
 928 exchangeable *distribution over partitions* and is called the CRP.

### 929 ▼ Definition 2.48 — Chinese restaurant process

930  
 931 A **Chinese restaurant process** is a sequential process that is an exchangeable distribu-  
 932 tion over partitions:

$$p(z_i = k | z_0, \dots, z_{i-1}) = \begin{cases} \frac{n_k}{\alpha + i} & \text{if } k \leq K_+ \\ \frac{\alpha}{\alpha + i} & \text{if } k > K_+ \end{cases} \quad (2.18)$$

933

934

935 The conditional probability of a cluster assignment  $z_i$  for data item  $y_i$  given the cluster  
 936 assignments  $z_0, \dots, z_{i-1}$  is proportional to the number of data items  $n_k$  assigned to an existing  
 937 cluster  $k$ , or proportional to  $\alpha$  for a new cluster.

938 The Chinese Restaurant Process is visualized in Figure 2.6.

**Figure 2.6:** The Chinese Restaurant Process with  $i$  customers already sitting down. A new customer  $y_{i=7}$  arrives and gets assigned,  $z_i$ . This is an existing table  $\{1, 2, 3\}$  with a probability proportional to the number of customers  $n_i$  sitting at that table:  $n_i/(\alpha + i)$ , or a new, empty table 4 with probability  $1/(\alpha + i)$ . In the visualized Chinese restaurant process the dispersion factor  $\alpha = 1$ .

### 939 C: Stick-breaking Representation of the Dirichlet process

#### ▼ Definition 2.49 — stick-breaking representation of the Dirichlet process

The stick-breaking representation of the Dirichlet process states that if

$$\phi_k \sim GEM(\alpha, 0) \quad (2.19)$$

$$\theta_k \sim H \quad (2.20)$$

$$G = \sum_{k=1}^{\infty} \phi_k \delta(\theta, \theta_k) \quad (2.21)$$

940 then  $G \sim DP(\alpha, H)$ .

941

942 The weights  $\phi_k$  are sampled from the stick-breaking process  $GEM(\alpha, 0)$  (see Definition 2.46).

943 The parameter values  $\theta_k$  are sampled from the base measure  $H$ . To sample from the Dirichlet

944 Process we have to sample these parameters with the given weights.

945 If the stick-breaking process is used as a prior for a mixture, then the cluster assignments  $z_i$

946 are sampled according to the mixing proportions  $\phi$ :

$$\phi \sim GEM(\alpha, 0) \quad (2.22)$$

$$\theta_k \sim H \quad (2.23)$$

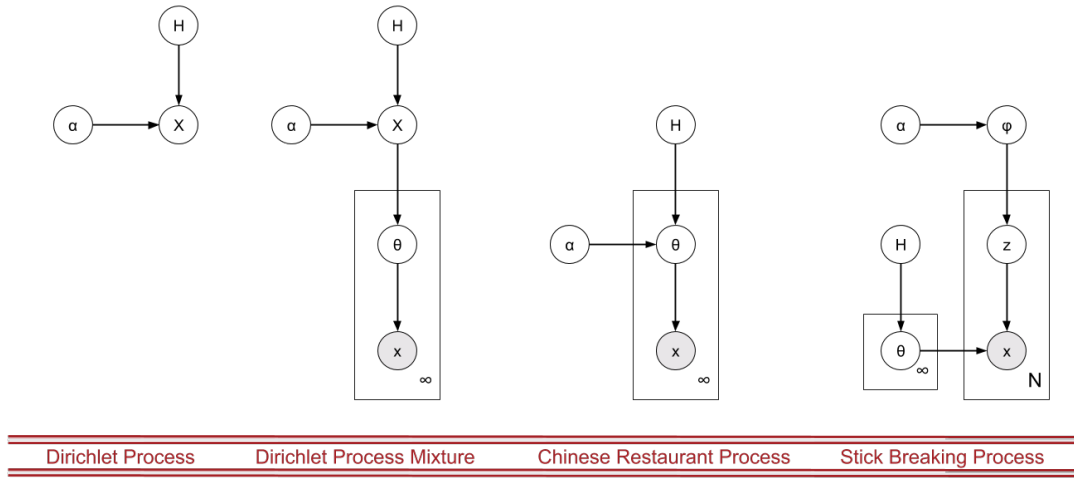

$$G = \sum_{k=1}^{\infty} \phi_k \delta(\theta, \theta_k) \quad (2.24)$$

$$z_i \sim Mult(\phi) \quad (2.25)$$

$$x_i \sim F(\theta_{z_i}) \quad (2.26)$$

947 Here  $\theta_k = \theta_{z_i}$  for observation with index  $i$  and cluster assignment  $k$ :  $z_i = k$ .

948 The Dirichlet process, the Dirichlet process as prior for a mixture model, the Chinese restau-  
949 rant process and the stick-breaking representation can be compared in Figure 2.7.

**Figure 2.7:** From left to right: (1) The Dirichlet process  $X \sim DP(\alpha, H)$ ; (2) The Dirichlet mixture model with  $X$  the prior for a sum  $\sum_i w_i p(x_i | \theta_i)$ ; (3) the Chinese restaurant process with  $X$  marginalized out; and (4) the Stick-breaking process with a distribution over partition sizes  $\pi$  and indicator variables  $z_i$ .

### 950 2.2.2 Beta Process

951 The Beta process is presented as a measure (Section A), is shown to have a sequential rep-  
 952 resentation in the form of the Indian buffet process (Section B), and a stick-breaking repre-  
 953 sentation (Section C).

#### 954 A: Beta Process as a Measure

955 A Beta process (Hjort, 1990) is a random process with a countably infinite collection of  
 956 weighted atoms in a space  $(X, \mathbb{B})$  with weights that are in between  $[0, 1]$ .

#### 957 ▼ Definition 2.50

958 Let  $(X, \mathbb{B})$  be a Borel space,  $\nu$  a finite measure, and  $\alpha > 0$  a scale parameter, then a  
 959 **Beta process** is a Lévy process on  $(X, \mathbb{B})$  with its Lévy measure  $\nu$  corresponding to the  
 960 density:  
 961

$$962 \nu(dw) = \alpha w^{-1} (1-w)^{\alpha-1} dw \quad (2.27)$$

962 with  $w > 0$ .

963  
 964 In Figure 2.8 the Beta Process is generated from a Completely Random Measure (see Sec-  
 965 tion 2.1.6) with a Lévy intensity defined on  $\Omega \otimes (0, 1)$  (Thibaux and Jordan, 2007). In this  
 966 case  $\Omega$  is the so-called base measure  $B_0$  and is assumed uniform over a bounded region. The  
 967  $(0, 1)$  space is equipped with an improper Beta distribution. It is called improper or degen-  
 968 erate because the scale parameter of the standard Beta distribution is set to zero. This has  
 969 the consequence that the integral is infinite:  $\nu(\Omega \otimes (0, 1)) = \infty$ . It is due to the fact that

**Figure 2.8:** A Completely Random Measure with a Lévy intensity defined on the product space  $\Omega \otimes (0, 1)$ . Here  $\Omega$  is a bounded interval on which the base measure  $B_0 = U(0, 100)$  is defined. On  $(0, 1)$  we define an improper beta distribution  $\alpha w^{-1}(1 - w)^{\alpha-1}$ . In this example  $\alpha = 10$ . This is how a Beta Process can be generated from a nonhomogeneous spatial Poisson point process. This has been visualized before (Jordan, 2010). The image is produced by rejection sampling using a homogeneous Poisson point process at  $\max(\nu)$  over  $w = [0.01, 0.9]$ . For  $w \rightarrow 0$  this maximum would go to  $\infty$  and all points would be rejected. Hence, the points should be denser for  $w$  around 0 and should be seen as an approximation of the actual process.

970 the density  $w^{-1}(1 - w)^{\alpha-1}$  goes to infinity for  $w \rightarrow 0$ . That means that a countable infinite  
 971 number of points can be obtained from the Poisson process.

972 The Beta process can be used as a prior for a feature or factorial model (Definition 2.42).  
 973 This is visualized in (Figure 2.9).

	$\theta_0$	$\theta_1$	$\theta_2$	$\theta_3$	$\theta_4$	$\theta_5$	$\theta_6$	$\theta_7$	$\theta_8$	$\theta_9$	sum
data 0	1	0	1	0	0	0	0	0	0	...	2
data 1	1	1	0	0	1	0	0	0	0	...	3
data 2	1	0	0	0	0	0	0	0	0	...	1
data 3	0	0	0	0	0	0	1	1	1	...	3
data 4	0	1	0	1	1	0	0	0	1	...	4
data 5	0	0	0	0	1	0	0	0	1	...	2

**Figure 2.9:** Matrix representation of a factorial model. At the horizontal axis the latent variables (potentially infinite number of features). At the vertical axis the data items. The rows sum up to nonnegative integers. A data item has multiple features.

## 974 B: Indian Buffet Process

975 The Beta process has a sequential representation in the form of the Indian Buffet Process:

### 976 ▼ Definition 2.51 — *Indian buffet process*

977  
978 An **Indian buffet process** is a sequential process that is an exchangeable distribution  
979 over sparse binary matrices:

$$p(z_{i,j} = k | z_{0,0}, \dots, z_{i-1,K_+}) = \begin{cases} \frac{n_{-i,k}}{i} & \text{if } k \leq K_+ \\ \frac{\lambda^{k_{new}} e^{-\lambda}}{k_{new}!} & \text{if } k > K_+ \end{cases} \quad (2.28)$$

980

981

982 Here  $\lambda = \alpha/i$ ,  $k_{new} = K_+ - k$ . The  $i$ 'th data item samples an existing column with a probability  
983 of the number of times it has been sampled before divided by its index,  $n_{-i,k}/i$ . It samples  
984 a new column with a probability according to a Poisson distribution,  $\lambda^{k_{new}} e^{-\lambda}/k_{new}!$ . The  
985 conditional form of the sequential presentation describes a closed-form solution for Gibbs  
986 sampling, section 2.3.4 (Ghahramani and Griffiths, 2005).

## 987 C: Stick-breaking Representation of the Beta process

### ▼ Definition 2.52 — *stick-breaking representation of the Beta process*

The **stick-breaking representation** of the Beta process states that if

$$\phi_{k,j} \sim GEM(\alpha, 0) \quad (2.29)$$

$$C_k \sim \text{Poisson}(\gamma) \quad (2.30)$$

$$\theta_{k,j} \sim \frac{1}{\gamma} H \quad (2.31)$$

$$G = \sum_{k=1}^{\infty} \sum_{j=1}^{C_k} \phi_{k,j} \delta(\theta, \theta_{k,j}) \quad (2.32)$$

988 then  $G \sim BP(\alpha, H)$ .

989

990 The Beta process is used in linguistics (He et al., 2013; Vanhainen and Salvi, 2012), computer  
991 vision (Zhou et al., 2011; Gao and Sun, 2013), risk assessment (Li et al., 2014), and medicin  
992 (Ross et al., 2014).

## 993 2.2.3 Gamma Process

994 The Gamma process is presented as a measure (Section A), is shown to have a sequential  
995 representation in the form of a multi-scoop Indian buffet process (Section B), and a stick-  
996 breaking representation (Section C).

## 997 A: Gamma Process as a Measure

998 A Gamma process is a random process with independent gamma distributed increments  
 999 (Ferguson, 1974). Below we provide a formal definition.

### 1000 ▼ Definition 2.53 — Gamma process

1001  
 1002 Let  $(X, \mathbb{B})$  be a Borel space,  $\nu$  a finite measure, and  $\alpha > 0$  a scale parameter, then a  
 1003 **Gamma process** is a Lévy process on  $(X, \mathbb{B})$  with its Lévy measure  $\nu$  corresponding to  
 1004 the density:

$$\nu(dw) = w^{-1}e^{-\alpha w}dw \quad (2.33)$$

1005 with  $w > 0$ .

**Figure 2.10:** A Completely Random Measure with a Lévy intensity defined on the product space  $\Omega \otimes \mathbb{R}$ . Here  $\Omega$  is a bounded interval on which the base measure  $B_0 = U(0, 100)$  is defined. On  $\mathbb{R}$  we define an improper gamma distribution  $w^{-1}e^{-\alpha w}$ . In this example  $\alpha = 1$ . This is how a Gamma Process can be generated from a nonhomogeneous spatial Poisson point process. The image is produced by rejection sampling in the same way as Figure 2.8.

1007 The Gamma process can be used as a prior for a counting model (Definition 2.43). This is  
 1008 visualized in (Figure 2.11).

	$\theta_0$	$\theta_1$	$\theta_2$	$\theta_3$	$\theta_4$	$\theta_5$	$\theta_6$	$\theta_7$	$\theta_8$	$\theta_9$	sum
data 0	4	0	3	0	0	0	0	0	0	...	7
data 1	1	1	0	0	1	0	0	0	0	...	3
data 2	2	0	0	0	0	0	0	0	0	...	2
data 3	0	0	0	0	0	4	1	0	0	...	5
data 4	0	0	0	2	0	0	0	0	0	...	2
data 5	0	0	0	0	0	4	0	0	6	...	10
data 6	0	0	0	0	0	4	0	0	0	...	4

**Figure 2.11:** Matrix representation of a counting model. At the horizontal axis the latent variables (potentially infinite number of features). At the vertical axis the data items. Each data item has one or more features and these features can occur multiple times.

#### 1009 **B: Multi-Scoop Indian Buffet Process**

1010 Find sequential representation. It is an Indian Buffet Process where the customers can pick  
1011 up multiple scoops from the same dish.

1012 (Zhou et al., 2012)

#### 1013 **C: Stick-breaking Representation of the Gamma process**

1014 The stick-breaking representation of the Gamma process introduces an additional Gamma  
1015 distribution that defines the number of times a feature is represented in a data object com-  
1016 pared to the Beta process, see Definition 2.54, (Roychowdhury and Kulis, 2015).

##### ▼ Definition 2.54 — *stick-breaking representation of the Gamma process*

The **stick-breaking representation** of the Gamma process states that if

$$\phi_{k,j} \sim GEM(\alpha, 0) \quad (2.34)$$

$$G_{k,j} \sim \text{Gamma}(\alpha + 1, c) \quad (2.35)$$

$$C_k \sim \text{Poisson}(\gamma) \quad (2.36)$$

$$\theta_{k,j} \sim \frac{1}{\gamma} H \quad (2.37)$$

$$G = \sum_{k=1}^{\infty} \sum_{j=1}^{C_k} G_{k,j} \phi_{k,j} \delta(\theta, \theta_{k,j}) \quad (2.38)$$

1017 then  $G \sim \text{GamP}(\alpha, H)$ .

1018

1019 The Gamma process is used in risk theory (Dufresne et al., 1991), spatial statistics (Wolpert  
 1020 and Ickstadt, 1998; Rao and Teh, 2009), erosion (Singpurwalla, 1997; Abdel-Hameed, 2012),  
 1021 and finance (Madan and Seneta, 1990; K  chler and Tappe, 2008).

#### 1022 2.2.4 Pitman-Yor Process

1023 The Pitman-Yor process (PYP) introduces another parameter  $d$  with respect to the Dirichlet  
 1024 process. It has been developed by Pitman and Yor as the two-parameter Poisson-Dirichlet  
 1025 distribution (Pitman and Yor, 1997). The Pitman-Yor process has the following definition.

##### ▼ Definition 2.55 — *Pitman-Yor process*

A Pitman-Yor process  $PY$  over a set  $S$  can be used to draw sample paths  $X$ :

$$X \sim PY(d, \alpha, H)$$

1026 with  $\alpha > -d$  a strength parameter,  $0 \leq d < 1$  a discount parameter, and  $H$  a measure  
 1027 on  $S$ .

1028

1029 The Pitman-Yor process generalizes the Dirichlet process. The Pitman-Yor process has a stick-  
 1030 breaking representation in which sticks are drawn from  $GEM(\alpha, \beta)$ . The Dirichlet process  
 1031 has a stick-breaking representation in which sticks are drawn from  $GEM(\alpha, 0)$ , see Def. 2.52.

##### ▼ Definition 2.56

The **stick-breaking representation** of the PYP states that if

$$\phi_k \sim GEM(\alpha, \beta) \tag{2.39}$$

$$\theta_k \sim H \tag{2.40}$$

$$G = \sum_{k=1}^{\infty} \phi_k \delta(\theta, \theta_k) \tag{2.41}$$

1032 then  $G \sim PYP(\alpha, H)$ .

1033

1034 The Pitman-Yor process is used in quite a few applications, such as language models (Teh  
 1035 et al., 2006), scene segmentation (Sudderth and Jordan, 2009), speech induction (Blunsom  
 1036 and Cohn, 2011), and time series (Bassetti et al., 2014).

#### 1037 2.2.5 Hierarchical Dirichlet Process

1038 The HDP extends the Dirichlet mixture model with a hierarchical structure (Teh et al., 2006).

##### ▼ Definition 2.57

A Hierarchical Dirichlet process  $HDP$  over a set  $S$  can be used to draw sample paths  $X$ :

$$G_0 \sim DP(\gamma, H)$$

$$X_i \sim DP(\alpha_0, G_0) \text{ for each group } i$$

with a Dirichlet Process with a general  $\gamma$  dispersion parameter and base distribution  $H$  as a measure on  $S$  of which the generated distributions  $G_0$  are used as base distribution for each group distribution  $X_i$ .

(a) Dirichlet Process Mixture Model. Each draw from the process corresponds to a parameter. Each parameter is associated with a distribution (in this case a Gaussian). The only freedom left to express by  $G_i$  is in the weights of those atoms. This reflects a decomposition in a structural and non-structural component.

**Figure 2.12:** The difference visualized between a Dirichlet Process mixture and a hierarchical Dirichlet process. It illustrates also that the input of a Dirichlet process does not have to be a continuous function. If it is a continuous distribution it will become a discrete distributed almost surely. If it is a discrete distribution, it will have atoms at the locations where the discrete distribution had its probability mass concentrated.

The hierarchical Dirichlet process uses the outcome of a Dirichlet Process as a starting point to define multiple distributions with atoms at the same locations, while they come equipped with different weights. So, the Dirichlet process on the lower level uses not a continuous distribution as input, but a discrete one, generated by the DP at the top layer. Note, that the Dirichlet Process will *generate* an almost surely (a.s.) discrete distribution, but it can also have a discrete distribution as *prior*  $H$ .

## 2.2.6 Comparison of Random Processes

The Dirichlet process (Section 2.2.1), the Beta process (Section 2.2.2), the Gamma process (Section 2.2.3), the Pitman-Yor process (Section 2.2.4), and the hierarchical Dirichlet process (Section 2.2.5) are not be compared on performance or computationally efficiency. The

processes each represent different assumptions on the model structure. The Dirichlet process is suited for clustering problems where observations have to be assigned to a single class. The Beta process is a good model for applications with combinatorial structure: features that are shared among multiple objects. The Gamma process is a model for applications with counting: features are shared among multiple objects and there is a number of features per object. The Pitman-Yor process fits clustering problems where the distribution over clusters sizes obeys a power law. The hierarchical Dirichlet process is a typical example of a process that can model additional structure within a cluster.

## 2.3 Inference

There will be six inference methods described, all sampling methods. Inverse transform sampling is described in Section 2.3.1. Rejection sampling in Section 2.3.2. Approximate Bayesian computation in Section 2.3.3. Gibbs sampling in Section 2.3.4. Metropolis-Hastings in Section 2.3.5. Split-Merge MCMC in Section 2.3.6. We rapport for every inference method the corresponding algorithm in pseudo code. We compare the inference methods in Section 2.3.7.

### 2.3.1 Inverse Transform Sampling

Let  $p(x)$  be a discrete probability distribution with two possible values  $x = f$  and  $x = g$ . The probability distribution sums up to one:  $\sum_v p(x = v) = 1$ . Sample from a uniform distribution  $u \sim U(0, 1)$ . If  $u < p(x = f)$  generate  $f$ , else generate  $g$ . This procedure samples  $f$  with probability  $p(x = f)$  and  $g$  with probability  $p(x = g)$ . This can be readily generalized to more than two values by making use of the cumulative distribution function. In Algorithm 1 we sample from  $f(x)$  by making use of the inverse cumulative distribution.

---

#### Algorithm 1 Inverse transform sampling for $f(x)$

---

```

1: procedure INVERSE TRANSFORM SAMPLING( $f(x)$ )           ▷ Distribution to sample from.
2:    $F(x) = P(X \leq x) \quad \forall x \in X$                    ▷ Create cumulative distribution function  $F(x)$ .
3:   for  $t = 1 \rightarrow T$  do
4:      $u \sim U(0, 1)$                                      ▷ Sample from uniform distribution.
5:      $x \sim F^{-1}(u)$                                      ▷ Sample  $x$  from (the inverse)  $F^{-1}(x)$ .
6:      $X = X \cup x$ 
7:   end for
8:   return  $X$                                              ▷  $X$  will have the distribution of  $f(x)$ .
9: end procedure

```

---

The term “inverse” stems from the fact that we return  $x$  (or  $f(x)$ ) given  $u$ . Inverse transform sampling is a common component in sampling methods. When one of the steps in an algorithm samples from a uniform distribution, it is often an inverse transform sampling step.

### 1079 2.3.2 Rejection Sampling

1080 Let  $f(x)$  be a complicated function from which it is hard to take samples. Let  $g(x)$  be a  
 1081 simple function that is easy to sample from. Then we can sample from  $f(x)$  by making  
 1082 sure  $Mg(x) \geq f(x)$ . The function  $Mg(x)$  is an *envelope* function. This sampling method  $S$   
 1083 generates the sample set  $X$  using  $f(x)$  and  $g(x)$ .

$$X = S(f(x), g(x)) \quad (2.42)$$

1084 The rejection sampling method (Halperin and Burrows, 1960) for  $f(x)$  is described in Algo-  
 1085 rithm 2.

---

#### Algorithm 2 Rejection sampling for $f(x)$

---

```

1: procedure REJECTION SAMPLING( $f(x), g(x)$ )      ▷ Target and proposal distribution.
2:   for  $t = 1 \rightarrow T$  do
3:      $x^t \sim g(x)$                                 ▷ Generate  $x^t$  from  $g(x)$ 
4:      $u \sim U(0, 1)$                                 ▷ Inverse transform sampling
5:      $p_0 = f(x)/(Mg(x))$ 
6:     if  $u < p_0$  then
7:        $X = X \cup x^t$                                 ▷ Accept
8:     end if
9:   end for
10:  return  $X$                                           ▷  $X$  will have the distribution of  $f(x)$ 
11: end procedure

```

---

1086 We can use rejection sampling to *sample* from the *posterior*  $f(\theta|x)$  given that we know  
 1087 the *exact* likelihood function and that we can *sample* from the prior. We know that we can  
 1088 sample from the posterior by sampling from  $p(\theta)p(x|\theta)$ . Moreover, we know that the prior  
 1089  $p(\theta)$  necessarily has to be larger than  $p(\theta)p(x|\theta)$  for any observation, because  $p(x|\theta)$  is a  
 1090 probability density function, hence for each  $x$  and  $\theta$  it is smaller than one. Hence we can  
 1091 use rejection sampling with  $Mg(x) \geq f(x)$  with  $M = 1$ ,  $p(\theta) = g(x)$  and  $p(x|\theta) = f(x)$ .

1092 We introduce the following notation. We make explicit that we need  $p(x|\theta)$  for each com-  
 1093 bination of observations and parameters, but that we only need to *sample* from the prior,  
 1094 which we indicate by a tilde,  $\sim p(\theta)$ .

$$\Theta = S(\sim p(\theta), p(x|\theta), x) \quad (2.43)$$

**Algorithm 3** Rejection sampling for  $f(\theta|x)$ 

---

```

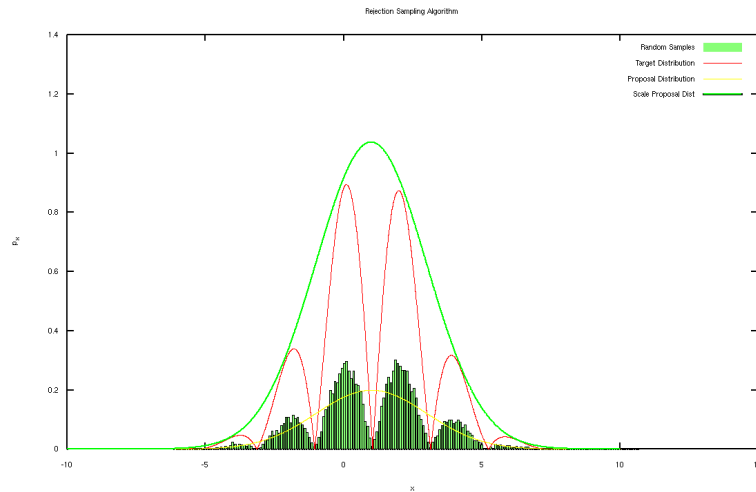

1: procedure REJECTION SAMPLING( $p(\theta), p(x|\theta), x$ )      ▷ Requires prior, likelihood and
   observations.
2:   for  $t = 1 \rightarrow T$  do
3:      $\theta^t \sim p(\theta)$                                 ▷ Generate  $\theta^t$  from prior
4:      $u \sim U(0, 1)$                                     ▷ Inverse transform sampling
5:      $p_0 = p(x|\theta)$ 
6:     if  $u < p_0$  then
7:        $\Theta = \Theta \cup \theta^t$                             ▷ Accept
8:     end if
9:   end for
10:  return  $\Theta$                                           ▷  $\Theta$  will have the distribution of  $f(\theta|x)$ 
11: end procedure

```

---

1095 In Algorithm 3 the envelope distribution  $p(\theta)$  and the target distribution  $p(\theta)p(x|\theta)$ , cancel  
 1096 in such way that only  $p(x|\theta)$  remains.

1097 Most examples illustrate rejection sampling by estimating the area of a circle, but let us  
 1098 visualize the method in the context of sampling (Figure 2.13).

**Figure 2.13:** A Gaussian is placed over the complex target probability density function. Subsequently the samples that fall in between these two ‘envelopes’ are rejected. This results in a sampling scheme that follows exactly the more complicated probability density function. Note that if the function is scaled by a factor, the sampling scheme stays the same. Such a scaling factor is only important if we want, for example, to know the area under the graph.

### 1099 2.3.3 Approximate Bayesian Computation

1100 In approximate Bayesian computation (ABC) (Rubin and Others, 1984) the likelihood func-  
 1101 tion does not need to be calculated<sup>2</sup> (Sisson and Fan, 2011). In contrast, it is assumed

<sup>2</sup>ABC is also called likelihood-free computation

that there is a model available that allows to generate observations given the (searched for) parameters. In ABC for each configuration of parameters a set of observations is generated.

$$\Theta = S(\sim p(\theta), X, \sim M(\theta), d(X^t, X), \epsilon) \quad (2.44)$$

Approximate Bayesian computation uses many tuning parameters. Its most salient characteristic though, is that it generates pseudo-observations through  $M(\theta)$  (see Algorithm 4).

---

**Algorithm 4** Approximate Bayesian computation
 

---

```

1: procedure APPROXIMATE BAYESIAN COMPUTATION( $p(\theta), X, M, d, \epsilon$ )    ▷ Requires prior,
   observations, model, distance function, and threshold.
2:   for  $t = 1 \rightarrow T$  do
3:      $\theta^t \sim p(\theta)$                                               ▷ Generate  $\theta$  from prior
4:      $X^t \sim M(\theta)$                                               ▷ Simulate observations  $X^t$  from model  $M$ 
5:      $\rho = d(X^t, X)$     ▷ Calculate distance between simulated and actual observations
6:     if  $\rho \leq \epsilon$  then
7:        $\Theta = \Theta \cup \theta^t$     ▷ Accept  $\theta^t$  if distance falls under threshold  $\epsilon$ .
8:     end if
9:   end for
10:  return  $\Theta$     ▷  $\Theta$  will have the distribution of  $f(\theta|X)$ 
11: end procedure
  
```

---

The term Bayesian reflects the fact that a prior is involved. The weight of this prior can be manipulated by the threshold  $\epsilon$ . If this threshold is set very low, the prior plays no role and only observations are taken into account. If  $\epsilon$  is set extremely high, all  $\theta$  coming from the prior will be accepted, and the actual observations are not used in the process. There are several disadvantages to approximate Bayesian computation.

- A set of simulated observations has to be compared with the actual observations. This becomes unwieldly if there are many observations.
- It is possible to use summary statistics rather than the observations themselves. If these are sufficient statistics there will be no information loss. If not, there will be information loss in practice.
- The distance function suffers from the curse of dimensionality. In the case that the dimensionality of the individual observations becomes high, or the number of parameters becomes large, it gets increasingly difficult to come up with a distance function which is efficient and accurate at the same time.

### 2.3.4 Gibbs Sampling

Gibbs sampling (Geman and Geman, 1984) is similar to the *coordinate descent* optimization algorithm (Wright, 2015). In coordinate descent a local minimum of a function is found by iteratively performing a line search along one coordinate direction at a time. Gibbs sampling

1124 optimizes over one variate in the multivariate probability distribution at a time. The update  
 1125 value is set and fixed. Then, the next variate is chosen in a round-robin like manner.

$$\Theta = S(X, \sim p(\theta_i | \theta_{-i}, X), \sim p(\theta), B) \quad (2.45)$$

1126 The Gibbs algorithm is given in Algorithm 5. Some explanation on the notation is as follows.  
 1127 The multiple parameters in the multivariate probability distribution are denoted by  $\theta$ . The  
 1128 parameters are denoted individually with  $\theta_i$ . The set of all parameters except for  $i$  is denoted  
 1129 by  $\theta_{-i}$ . If we sample a parameter we write  $\theta^t$  with  $t$  the iteration or sampling round. The  
 1130 set of parameter samples has capital letter  $\Theta$ .

---

**Algorithm 5** Gibbs sampling
 

---

```

1: procedure GIBBS SAMPLING( $p(\theta_i | \theta_{-i}, X), p(\theta), X, B$ )           ▷ Requires parameters,
   observations and burn-in.
2:    $\theta^0 \sim p(\theta)$                                            ▷ Set parameters to some initial value
3:   for  $t = 1 \rightarrow T$  do
4:     for  $i = 1 \rightarrow k$  do
5:        $\theta_i^t \sim p(\theta_i^{t-1} | \theta_{-i}^t, X)$            ▷ Generate  $\theta_i^t$  from the full conditional probability
6:     end for
7:      $\Theta = \Theta \cup \theta^t$ 
8:   end for
9:    $\Theta_{B:T} \in \Theta$                                            ▷ Get  $\Theta_T$  set, from burn-in  $B$  to end of run  $T$ 
10:   $\Theta \sim \Theta_{B:T}$                                            ▷ Sample  $\Theta$  from correlated  $\Theta_{B:T}$ 
11:  return  $\Theta$ 
12: end procedure
  
```

---

1131 Gibbs samples are Markovian. This means that the conditional probability only takes into  
 1132 account values at the previous time step  $t - 1$ . When running the Gibbs sampling algorithm  
 1133 long enough, it will visit all possible states eventually. The Markovian property has an un-  
 1134 desired side effect. It makes subsequent steps correlated. Hence when finally extracting the  
 1135 parameter probabilities, it is important to skip multiple steps to remove the temporal cor-  
 1136 relations. It is also important to run the algorithm for a while after its start. In that case it  
 1137 does not suffer from a bad choice of initial parameter values. Disregarding the first samples  
 1138 is called burn-in. In words, Gibbs sampling works by having the algorithm spend time in  
 1139 parts of the space proportionally to the probability of getting into that part of the space.

1140 In the physics literature Gibbs sampling is known as Glauber dynamics or the heat bath al-  
 1141 gorithm. First, observe that Gibbs sampling does not necessary require an actual calculation  
 1142 of the conditional probability in all cases. The obvious exception is for the observations,  
 1143 which are already known. Second, observe that a neat optimization procedure arises when  
 1144 conjugate priors are used. A conjugate prior leads to a posterior distribution that can be de-  
 1145 scribed analytically. In such a case it is computationally unnecessary to perform sampling.  
 1146 It is much faster to use the actual available analytic description. This is commonly called  
 1147 collapsed Gibbs sampling.

### 1148 2.3.5 Metropolis-Hastings Sampling

1149 Metropolis-Hastings (Metropolis et al., 1953) is one of the most well-known Markov chain  
 1150 Monte Carlo (MCMC) algorithms. An MCMC algorithm uses a Markov chain (see Gibbs  
 1151 sampling, Section 2.3.4) and combines this with a stochastic (Monte Carlo) component.  
 1152 This sampling method can be used for high-dimensional distributions. Metropolis-Hastings  
 1153 calculates an acceptance factor  $\alpha$  which takes into account if a step should be taken according  
 1154 to a predefined proposal distribution. In case this step is not accepted, the current sample is  
 1155 resampled (see Algorithm 6).

$$\Theta = S(X, \theta^0, Q(\theta^{t+1}|\theta^t), f(\theta, X)) \quad (2.46)$$

1156 Here we need  $Q(\theta^{t+1}|\theta^t)$  explicitly as well as samples from it.

---

#### Algorithm 6 Metropolis-Hastings sampling

---

```

1: procedure METROPOLIS-HASTINGS SAMPLING( $\theta^0, X, Q, f$ )  $\triangleright$  Requires initial parameters,
   observations, proposal distribution, and function proportional to desired distribution
2:   for  $t = 1 \rightarrow T$  do
3:      $\theta^{t+1} \sim Q(\theta^{t+1}|\theta^t)$   $\triangleright$  Sample from proposal distribution  $Q$ 
4:      $\alpha = \frac{f(\theta^{t+1}, X^{t+1})Q(\theta^t|\theta^{t+1})}{f(\theta^t, X^t)Q(\theta^{t+1}|\theta^t)}$   $\triangleright$  Calculate acceptance
5:      $u \sim U(0, 1)$   $\triangleright$  Inverse transform sampling
6:     if  $\alpha > u$  then
7:        $\Theta = \Theta \cup \theta^{t+1}$   $\triangleright$  Accept  $\theta^{t+1}$ 
8:     else
9:        $\Theta = \Theta \cup \theta^t$   $\triangleright$  Reuse previous sample (note, different from rejection)
10:    end if
11:  end for
12:  return  $\Theta$   $\triangleright$   $\Theta$  will be samples from the distribution  $f(\theta|x)$ 
13: end procedure

```

---

1157 A particular choice of a Metropolis-Hastings step is that of a proposal distribution that does  
 1158 not depend on the state of the chain. This is already suggested by Hastings and is called the  
 1159 independence sampler.

### 1160 2.3.6 Split-Merge MCMC Sampling

1161 The discussed sampling methods do not assume much structure in the model. This means  
 1162 that in hierarchical models sampling either occurs through updating the to-be-estimated  
 1163 quantities by iterating over every single observation or over every single cluster. This has  
 1164 a disadvantage, the procedure in which a cluster is split into two clusters is very slow by  
 1165 moving data points one by one from an old to a new cluster. Much more efficient sampling  
 1166 methods can be designed if we would be able to handle large chunks of cluster assignments  
 1167 at once.

Split-merge samplers are such methods that can update cluster assignments for multiple observations at once. These samples adjust the acceptance method in the Metropolis-Hastings algorithm. Split-Merge sampling is described in Algorithm 7.

---

**Algorithm 7** Split-Merge MCMC sampling
 

---

```

1: procedure SPLIT-MERGE MCMC SAMPLING( $\theta^0, X, Q, f$ )  ▷ Requires initial parameters,
   observations, proposal distribution, and function proportional to desired distribution

3:      $i \sim D(0, N - 1)$   ▷ Sample observation  $i$  discretely
4:      $j \sim D(0, N - 1)$   ▷ Sample observation  $j$  discretely
5:     if  $c_i == c_j$  then
6:        $c_{old} = c_i$ 
7:        $\theta_{c_{new}}^{t+1} \sim Q(\theta^{t+1} | \theta^t)$   ▷ Sample from proposal distribution  $Q$ 
8:       for  $k \in c_{old}$  do
9:          $c_k \sim C(c_{old}, c_{new})$   ▷ Assign to new cluster categorically
10:      end for
11:     else
12:        $c_{merge} = c_i$ 
13:       for  $k \in c_j$  do
14:          $c_k = c_{merge}$   ▷ Assign all to first cluster
15:       end for
16:     end if
17:      $\alpha = \frac{f(\theta^{t+1}, X^{t+1})Q(\theta^{t+1} | \theta^t)}{f(\theta^t, X^t)Q(\theta^t | \theta^{t+1})}$   ▷ Calculate acceptance
18:      $u \sim U(0, 1)$   ▷ Inverse transform sampling
19:     if  $\alpha > u$  then
20:        $\Theta = \Theta \cup \theta^{t+1}$   ▷ Accept  $\theta^{t+1}$ 
21:     else
22:        $\Theta = \Theta \cup \theta^t$   ▷ Reuse previous sample (note, different from rejection)
23:     end if
24:   end for
25:   return  $\Theta$   ▷  $\Theta$  will be samples from the distribution  $f(\theta | x)$ 
26: end procedure

```

---

The exact acceptance probability depends on the model. For the mixture model with a Dirichlet Process as prior, its performance is further improved by adjusting the assignment process from random to observation-supported by introducing intermediate restricted Gibbs sampling steps (Jain and Neal, 2004, 2007). Similarly, there are other variants that incorporate data fit to the splitting step. Labels can for example be calculated sequentially (Dahl, 2003) or methods can be used that postulate subcluster structure within clusters to optimize inference over split and merge sets (Chang and Fisher III, 2013).

### 1178 **2.3.7 Comparison of the Six Inference Methods**

1179 In robotic vision the type of data we are obtaining from depth sensors are point clouds. To  
1180 perform inference over objects made out of point clouds, clustering algorithms benefit from  
1181 two sampling strategies. If conjugate probability densities are used, Gibbs sampling, or col-  
1182 lapsed Gibbs sampling can be used (Section 2.3.4). If the model becomes more complicated  
1183 and nonconjugate split-merge sampling will likely accelerate the inference (Section 2.3.6).

## 1184 **2.4 Chapter Conclusions**

1185 Chapter 3 describes Gibbs sampling to perform inference over an infinite set of lines. Gibbs  
1186 sampling requires conditional probabilities. These are given in closed-form because there  
1187 is a conjugate description of the line parameters given the points that form the lines in this  
1188 application.

1189 Chapter 4 describes Split-Merge MCMC sampling to perform inference over an infinite set  
1190 of line segments. The parameters for line segments do not have a conjugate description.  
1191 Metropolis-Hastings can be used to perform inference over the line segments, but the search  
1192 space is quite large. The Split-Merge MCMC method performs faster inference than Metropolis-  
1193 Hastings because it is able to split and merge line segments (with multiple points ascribed  
1194 to them) at once.

The nonparametric Bayesian models from the literature (Chapter 2) can be applied to perform inference over point clouds. An example of a point cloud are points distributed over lines in a two-dimensional space. Traditionally, RANSAC and the Hough transform have been used to perform inference over such lines. This chapter uses a nonparametric Bayesian model to perform inference over a countably infinite number of lines. Given a prior with respect to the noise and distribution of points over the lines, Bayesian inference describes the optimal procedure to perform line fitting.

1220

The infinite line model describes a collection of lines with a Dirichlet process as prior (Sect. 3.1). Inference in the infinite line model is performed through Gibbs sampling. (Sect. 3.2). Gibbs sampling over parameters converges slowly. It can be accelerated through sampling over clusters (Sect. 3.3). The inference method results are measured using clustering performance measures (Sect. 3.4). The chapter summarizes the findings (Sect. 3.5) and introduces extensions which will be handled in the next chapters.

In computer vision and particularly in robotics, traditionally the task of line detection has been performed through sophisticated, but ad-hoc methods. We will give two examples

of such methods. RANSAC (Bolles and Fischler, 1981) is a method that iteratively tests a hypothesis. A line is fitted through a subset of points. Then other points that are in consensus with this line (according to a certain loss function) are added to the subset. This procedure is repeated till a certain performance level is obtained. The Hough transform (Hough, 1962) is a deterministic approach which maps points in the image space to curves in the so-called Hough space of slopes and intercepts. A line is extracted by getting the maximum in the Hough space.

There are four main problems with these methods. First, the extension of RANSAC or Hough to the detection of multiple lines is nontrivial (Zhang and Kősecká, 2007; Gallo et al., 2011; Chen et al., 2001). Second, the noise level is hardcoded into model parameters and it is not possible to incorporate knowledge about the nature of the noise. Third, it is hard to extend the model to hierarchical forms, for example, to lines that form more complicated structures such as squares or volumetric forms. Fourth, there are no results known with respect to any form of optimality of the mentioned algorithms.

In this chapter we postulate a method to perform inference over the number of lines and over the fitting of points on that line using the nonparametric Bayesian methods from chapter 2.

### 3.1 Infinite Line Model

The Dirichlet Process described as prior for a mixture distribution (Fig. 2.6 in section 2.2.1) can be used in this particular case as a prior for the distribution of points over a countably infinite set of lines.

**Figure 3.1:** The Infinite Line Model in the Chinese Restaurant Process representation (compare with Fig. 2.6). Top:  $\alpha$ , the concentration parameter of the Dirichlet process. Bottom, left to right:  $w_i$ , the observation, an individual point in a 2D space;  $\theta_i$ , the parameters (intercept, slope) of the line belonging to observation  $w_i$ ;  $H$ , the base distribution from which line parameter values are sampled.

The infinite line model is visualized (Fig. 3.2) through plate notation (Buntine, 1994). In section 3.1.1 it is described how  $\theta_i$  is sampled from  $H$  and  $\alpha$ . In section 3.1.2 it is described how  $w_i$  is sampled from  $\theta_i$ . In section 3.1.3 the prior  $H$  for  $\theta_i$  is described.

#### 3.1.1 Posterior Predictive for a Line given Other Lines

Let us reiterate the definition of the Dirichlet process. Let  $H$  be a distribution over  $\Theta$ , let  $\alpha$  be scalar. The Dirichlet process generates a distribution  $G \sim DP(\alpha, H)$ :

$$G(\theta_1, \dots, \theta_\infty) \sim DP(\alpha, H(\theta_1, \dots, \theta_\infty)) \quad (3.1)$$

1249 A Dirichlet process assigns a Dirichlet distribution to every parameter partition  $\Theta_1, \dots, \Theta_r$ :

$$(G(\Theta_1), \dots, G(\Theta_r)) \sim Dir(\alpha H(\Theta_1), \dots, \alpha H(\Theta_r)) \quad (3.2)$$

1250 The Dirichlet is conjugate to the categorical:

$$(G(\Theta_1), \dots, G(\Theta_r)) \mid \theta_1, \dots, \theta_n \sim Dir(\alpha H(\Theta_1) + n_1, \dots, \alpha H(\Theta_r) + n_r) \quad (3.3)$$

$$n_k = \sum_{j=1}^n \delta_{\theta_j}(\Theta_k)$$

1251 In the above notation,  $\delta_{\theta_j}(\Theta_k)$  is a Dirac measure (a generalization of the Dirac delta func-  
1252 tion), also known as an indicator function. Given a set  $\Theta_k$  with a  $\sigma$ -algebra over subsets of  
1253  $\Theta$ :

$$\delta_{\theta_j}(\Theta_k) = 1_{\Theta_k}(\theta_j) = \begin{cases} 1 & \text{if } \theta_j \in \Theta_k \\ 0 & \text{if } \theta_j \notin \Theta_k \end{cases} \quad (3.4)$$

1254 The posterior for the Dirichlet process base distribution and dispersion parameter is a Dirich-  
1255 let process with adjusted parameters:

$$G(\cdot) \mid \theta_1, \dots, \theta_n \sim DP\left(\alpha + n, \frac{\alpha}{\alpha + n} H(\cdot) + \frac{n}{\alpha + n} \frac{\sum_{j=1}^n \delta_{\theta_j}(\cdot)}{n}\right) \quad (3.5)$$

1256 The posterior base distribution  $G$  is a weighted average between the prior base distribution  
1257  $H$  and the empirical distribution  $n^{-1} \sum_{j=1}^n \delta_{\theta_j}$  with the weights respectively  $\alpha$  and  $n$  (nor-  
1258 malized). The dispersion parameter  $\alpha$  is updated to  $\alpha + n$ . Note that  $\delta_{\theta_j}(\cdot)$  is a distribution,  
1259 the Dirac measure Eq. 3.4.

1260 The posterior predictive for a new parameter  $\theta_{n+1}$  has the form:

$$P(\theta_{n+1} \in \Theta_k \mid \theta_1, \dots, \theta_n) = \frac{1}{\alpha + n} \left( \alpha H(\Theta_k) + \sum_{j=1}^n \delta_{\theta_j}(\Theta_k) \right) \quad (3.6)$$

1261 In other words, the posterior predictive of  $\theta_{n+1}$  given the parameters  $\theta_1, \dots, \theta_n$  in Eq. 3.6 has  
1262 exactly the same form as the posterior base distribution  $G$  given the parameters  $\theta_1, \dots, \theta_n$   
1263 (Blackwell and MacQueen, 1973) in Eq. 3.5, namely:

$$\theta_{n+1} \mid \theta_1, \dots, \theta_n \sim \frac{1}{\alpha + n} \left( \alpha H(\theta_{n+1}) + \sum_{j=1}^n \delta(\theta_j - \theta_{n+1}) \right) \quad (3.7)$$

1264 A normal Dirac delta function  $\delta(\theta_j - \theta_{n+1})$  can be used here, which is only non-zero when  
 1265  $\theta_j$  is equal to  $\theta_{n+1}$ .

1266 Equivalently, if we describe  $\theta_n$  conditioned on  $\theta_1, \dots, \theta_{n-1}$  we have to run over  $n - 1$  rather  
 1267 than  $n$  parameters:

$$\theta_n \mid \theta_1, \dots, \theta_{n-1} \sim \frac{1}{\alpha + n - 1} \left( \alpha H(\theta_n) + \sum_{j=1}^{n-1} \delta(\theta_j - \theta_n) \right) \quad (3.8)$$

1268 Due to the exchangeability property we can also consider any other parameter update (Neal,  
 1269 2000):

$$\theta_i \mid \theta_{-i} \sim \frac{1}{\alpha + n - 1} \left( \alpha H(\theta_i) + \sum_{j \neq i} \delta(\theta_j - \theta_i) \right) \quad (3.9)$$

1270 The notation  $\theta_{-i}$  means every parameter  $\theta$  except for the one equal to  $\theta_i$ .

### 1271 3.1.2 Likelihood of Data given a Line

1272 The likelihood of data given line parameters is defined to be according to the **Bayesian linear**  
 1273 **regression** model. The Bayesian linear regression model for a single line (Box and Tiao,  
 1274 2011) assumes a linear relationship between the independent  $x_i$  and dependent variables  
 1275  $y_i$  with Gaussian noise added in the  $y$ -direction. The individual points  $i$  are drawn from a  
 1276 Normal distribution:

$$y_i \sim \mathcal{N}(x_i \beta, \sigma^2) \quad (3.10)$$

1277 The (column) vector  $\beta$  maps the (row) vector with independent variables  $x_i$  to the depen-  
 1278 dent variable  $y_i$ . The noise is normally distributed with standard deviation  $\sigma$  along the  
 1279 dimension of the dependent variable.

1280 In a 2D point cloud the point  $p$  is represented by  $(x_p, y_p)$ . The points are mapped into an  
 1281 intercept-slope representation through defining  $X_i = [1, x_p]$  and  $y_i = y_p$ . The vector  $\beta$  will  
 1282 then contain the  $y$ -intercept as the first value, the slope as the second value.

1283 All observations that belong to the same single line lead to a likelihood function that corre-  
 1284 sponds to a normally distributed random variable with  $y$  and  $X$  as parameters:

$$p(y \mid X, \beta, \sigma^2) \propto \sigma^{-n} \exp \left( -\frac{1}{2\sigma^2} (y - X\beta)^T (y - X\beta) \right) \quad (3.11)$$

1285 The dependent variable is now a column vector of values  $y$  and each observation has a row  
 1286 of independent variables in  $X$ . The vector  $\beta$  and the standard deviation  $\sigma$  are shared across  
 1287 all observations. The term  $y - X\beta$  is written out like this:

$$\begin{pmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{pmatrix} - \begin{pmatrix} 1 & x_1 \\ 1 & x_2 \\ \vdots & \vdots \\ 1 & x_n \end{pmatrix} \begin{pmatrix} \beta_0 \\ \beta_1 \end{pmatrix} \quad (3.12)$$

1288 Note that Eq. 3.11 has exactly the same form for a single point or multiple points that belong  
 1289 to the same line. Hence, we have the probability of a point  $w_i$  given the line parameters  
 1290  $\theta_k = (\beta_k, \sigma_k)$ :

$$F(w_i, \theta_k) = p(w_i | \theta_k) = p(w_i | \beta_k, \sigma_k^2) = p(y_i | X_i, \beta_k, \sigma_k^2) \quad (3.13)$$

1291 To get the full distribution  $p(w_i, \beta, \sigma^2)$  we will need also  $p(\beta, \sigma^2)$ .

### 1292 3.1.3 Conjugate Prior for a Line

1293 The conjugate prior for the likelihood in Eq. 3.11 is a product of a prior for the standard  
 1294 deviation  $p(\sigma)$  and the conditional probability of the line coefficients given the standard  
 1295 deviation  $p(\beta | \sigma^2)$ .

$$p(\sigma^2, \beta) = p(\sigma^2)p(\beta | \sigma^2) \quad (3.14)$$

1296 The standard deviation  $\sigma$  is sampled from an Inverse-Gamma (IG) distribution:

$$p(\sigma) \propto (\sigma^2)^{-(\nu_0/2+1)} \exp\left(-\frac{1}{2\sigma^2} \nu_0 s_0^2\right) \quad (3.15)$$

1297 This is an  $IG(a_0, b_0)$  with  $a_0 = \nu_0/2$  and  $b_0 = 1/2 \nu_0 s_0^2$ . The conditional with respect to the  
 1298 line coefficients has a normal distribution as prior:

$$p(\beta | \sigma^2) \propto \sigma^{-n} \exp\left(-\frac{1}{2\sigma^2} (\beta - \mu_0)^T \Lambda_0 (\beta - \mu_0)\right) \quad (3.16)$$

1299 Let us collect  $\Lambda_0, \mu_0, a_0, b_0$  into  $\lambda_0$ , we have now a description of our base distribution  $H$ :

$$H(\theta_k) = NIG(\theta_k; \lambda_0) \quad (3.17)$$

1300 NIG is an abbreviation of the Normal-Inverse-Gamma distribution. The standard deviation  
 1301 is sampled from the Gamma distribution with  $a_0$  and  $b_0$  as hyperparameters and the line  
 1302 coefficients from a Normal distribution:

$$\begin{aligned} \sigma_k &= \tau_k^{-1/2} & \tau_k &\sim \mathcal{G}(a_0, b_0) \\ \mu_k &\sim \mathcal{N}(\mu_0, \sigma^2 \Lambda_0^{-1}) \end{aligned} \quad (3.18)$$

### 1303 3.1.4 Posterior Predictive for a Line given Data

1304 Due to the fact that it is a conjugate distribution we have a simplified description for updating  
 1305 the parameters at once, given a set of observations. The sufficient statistics are updated  
 1306 (Minka, 2000) according to:

$$\begin{aligned}\Lambda_n &= (X^T X + \Lambda_0) \\ \mu_n &= \Lambda_n^{-1}(\Lambda_0 \mu_0 + X^T y) \\ a_n &= a_0 + n/2 \\ b_n &= b_0 + 1/2(y^T y + \mu_0^T \Lambda_0 \mu_0 - \mu_n^T \Lambda_n \mu_n)\end{aligned}\tag{3.19}$$

1307 Let us collect  $\Lambda_0, \mu_0, a_0, b_0$  into  $\lambda_0$  and  $\Lambda_n, \mu_n, a_n, b_n$  into  $\lambda_n$ . Let us collect a set of our obser-  
 1308 vations and  $(X, y)_k$  into  $w_k$ . The update for the sufficient statistics can then be summarized  
 1309 as:

$$\lambda_n = U_{ss}(\lambda_0, w)\tag{3.20}$$

1310 If we combine this update with sampling  $\theta_k$  from  $\lambda_n$  according to Eq. 3.17, then we obtain:

$$p(\theta_k | \lambda_0, w_k) \propto F(w_k, \theta_k) H(\theta_k; \lambda_0) = p(\theta_k | \lambda_n) = NIG(\theta_k; \lambda_n)\tag{3.21}$$

1311 Sampling of  $NIG(\theta_k; \lambda_n)$  is as in Eq. 3.18, but with  $\lambda_n$  rather than  $\lambda_0$ .

1312 Let us integrate over  $\theta$  (through the function  $H$ ):

$$Q(w_k, \lambda_0) = \int_{\Theta} F(w_k, \theta) dH(\theta; \lambda_0)\tag{3.22}$$

## 1313 3.2 Inference for the Infinite Line Model

1314 The posterior predictive for parameters (see Eq. 3.9) combined with observations  $w_i$  is de-  
 1315 scribed by:

$$p(\theta_i | \theta_{-i}, w_i) \propto r_i H_i(\theta_i) + \sum_{j \neq i} L_{i,j} \delta(\theta_j - \theta_i)\tag{3.23}$$

1316 The posterior is proportional (indicated by  $\propto$ ) to three terms. First, the  $\alpha$  weighted posterior  
 1317 predictive  $r_i$  for a new cluster. Second, the posterior to sample from  $H_i(\theta_i)$  with probability  
 1318  $r_i$ . Third, the likelihood of an observation given a line  $L_{i,j}$ :

$$r_i = \alpha Q(w_i, \lambda_0) = \alpha \int_{\Theta} F(w_i, \theta) dH(\theta)\tag{3.24}$$

1319 The posterior  $H_i(\theta)$  is the normalized product of the prior distribution  $H(\theta_i)$  with the like-  
 1320 lihood  $F(w_i, \theta_i)$  for a single observation  $w_i$ .

$$H_i(\theta_i) \propto H(\theta_i)F(w_i, \theta_i) \quad (3.25)$$

$$L_{i,j} = F(w_i, \theta_j) \quad (3.26)$$

1321 Sampling a new cluster parameter from  $H_i(\theta_i)$  is done with probability:

$$p(\theta_{new}) = \frac{r_i}{r_i + \sum_{j \neq i} L_{i,j}} \quad (3.27)$$

1322 We can use this to derive the parameters  $\theta_i$ .

1323 This Gibbs algorithm is described in its general form before (Neal, 2000) (Algorithm 1). We  
 1324 perform a loop in which for  $T$  iterations each  $\theta_i$  belonging to observation  $w_i$  is updated  
 1325 in sequence. First, the posterior predictive for  $w_i$  given the hyperparameters  $p(w_i | \lambda_0)$  is  
 1326 calculated. Second, the likelihood  $L_{i,j}$  for all  $\theta_j$  given  $w_i$  (with  $j \neq i$ ) is calculated. Third,  
 1327 the fraction with  $r_i$  defines if  $\theta_i$  will be sampled from a new cluster or if one of the existing  
 1328 clusters will be sampled. Fourth, a new cluster is sampled, the sufficient statistics are up-  
 1329 dated with information on  $w_i$  and thereafter  $\theta$  is sampled from a Normal-Inverse-Gamma  
 1330 distribution with the updated hyperparameters. That, or an existing cluster will be sampled.

**Figure 3.2:** The Infinite Line Model in the stick-breaking representation (compare with Fig. 2.6). From left to right:  $\alpha$ , the concentration parameter of the Dirichlet process;  $(\phi_1, \dots, \phi_k)$ , the partition of points over lines;  $z_i$ , the assignment parameters that link observation  $w_i$  with line  $k$ ;  $w_i$ , the observation, an individual point with  $x$  and  $y$  coordinates;  $\theta_k$ , the parameters of line  $k$ ;  $\lambda_0$ , the base measure from which the line parameter values are sampled.

### 1331 3.3 Accelerating Inference for the Infinite Line Model

1332 It is also possible to iterate only over the clusters. The derivation takes a few steps (Neal,  
1333 2000) but leads to a simple update for the component indices that only depends on the  
1334 number of data items per cluster, the parameter  $\alpha$ , and the data.

```

---

1335 The probability to sample from a cluster depends on the number of items in that cluster (the  
1336 current data item excluded). This is expressed in equation 3.28.

$$p(c_i = c \text{ and } c_i = c_j \text{ and } i \neq j \mid c_{-i}, w_i, \alpha, \theta) \propto \frac{n_{c,-i}}{\alpha + n - 1} F(w_i \mid \theta_i) \quad (3.28)$$

1337 The probability to sample a new cluster only depends on  $\alpha$  and the total number of data  
 1338 items. This is described in equation 3.29.

$$p(c_i \in \Omega(c) \text{ and } c_i \neq c_j \text{ and } i \neq j \mid c_{-i}, \alpha) \propto \frac{\alpha}{\alpha + n - 1} \int F(w_i \mid \theta_i) dH(\theta) \quad (3.29)$$

1339 Here  $\Omega(c)$  denotes all admitted values for  $c_i$ .

1340 The importance of conjugacy is obvious from Eq. 3.29, it will lead to an analytic form of the  
 1341 integral. The inference method using equations 3.28 and 3.29 is described in section ??.

1342 Directly sampling over the clusters is described in its general form (Neal, 2000) (Algo-  
 1343 rithm 2).

1344 Rather than updating each  $\theta_i$  per observation  $w_i$ , an entire cluster  $\theta_k$  is updated. In Algo-  
 1345 rithm 8 the update of a cluster would require a first observation to generate a new cluster  
 1346 at  $\theta_j$  and then moving all observations of the old cluster  $\theta_i$  to  $\theta_j$ .

1347 Algorithm 9 follows the same procedure in excluding  $w_i$  from calculating the likelihood. This  
 1348 requires the previously mentioned “downdate” from the corresponding sufficient statistics.  
 1349 In Algorithm 9 after all observations have been iterated over and assigned the corresponding  
 1350 cluster  $k$ , an outer loop iterates over all clusters to obtain new parameters  $\theta$  from the NIG  
 1351 prior.

## 1352 3.4 Performance of the Infinite Line Model

1353 The Infinite Line Mixture Model (see section ??) is able to fit an infinite number of lines  
 1354 through a point cloud in two dimensions. These lines are no line segments, but infinite  
 1355 lines. However, to test the model a variable number of lines are generated of a length that is  
 1356 considerably larger compared to the spread caused by the standard deviation of points from  
 1357 that line.

1358 As described before, Gibbs sampling leads to correlated samples. We choose to get the  
 1359 Maximum A Posterior estimates for our clusters by picking the median values for all the  
 1360 parameters involved.

### 1361 3.4.1 Clustering Performance

1362 The results are measured using conventional metrics for clustering performance. For exam-  
 1363 ple the Rand Index describes the accuracy of cluster assignments (Rand, 1971):

$$R = \frac{a + b}{a + b + c + d} \quad (3.30)$$

1364 Here  $a$  numbers the pair of points that belong to the same cluster, both at ground truth as  
1365 well as after the inference procedure. Likewise  $b$  numbers the pair of points that belong to  
1366 different clusters in both sets. The values  $c$  and  $d$  describe discrepancies between the ground  
1367 truth and the results after inference. A Rand Index of one means that there have been no  
1368 mistakes.

1369 The clustering performance is separate from the line estimation performance. If the points  
1370 are not properly assigned, the line will not be estimated correctly. Due to the fact that line  
1371 estimation has this secondary effect, this performance is not taken into account. Moreover,  
1372 from lines that generated only a single, or very few points, we can extract point assignments,  
1373 but line coefficients are impossible to derive. This would lead to introducing a threshold  
1374 for the number of points per cluster. Moreover, the performance would then need to be  
1375 measured by weighting the fitting versus the assignment.

1376 The performance of Algorithm 1 can be seen in Fig. 3.3 and is rather disappointing. On  
1377 average the inference procedure agrees upon the ground truth for 75% of the cases consid-  
1378 ering the Rand Index. Moreover, if we adjust for chance as with the Adjusted Rand Index,  
1379 the performance drops to only having 25% correct!

1380 Algorithm 2 leads to stellar performance measures (Fig. 3.4). Apparently updating entire  
1381 clusters at once with respect to their parameter values leads at times to perfect clustering,  
1382 bringing the performance metrics close to their optimal values.

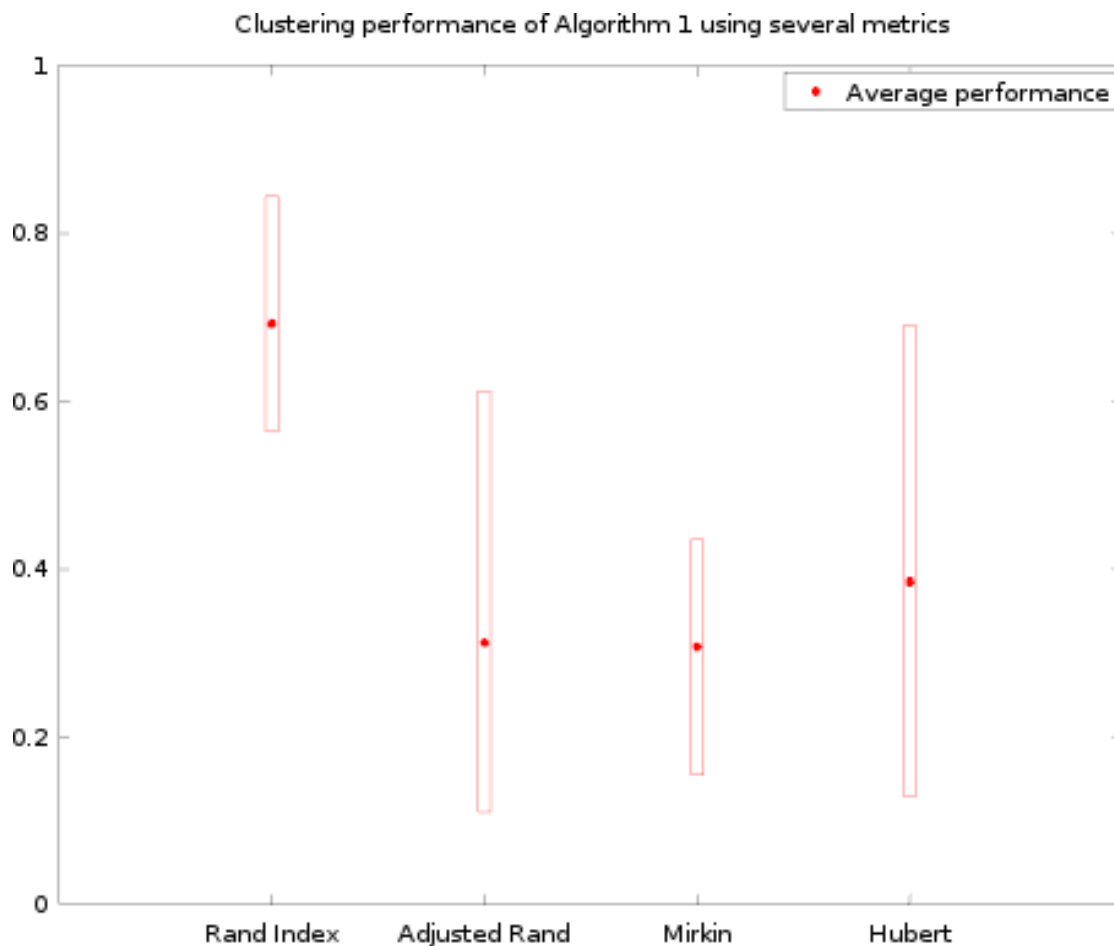

1383 The lack of performance of Algorithm 1 is not only caused by slower mixing (time required to  
1384 reach the steady state distribution). Also when allowing it ten times the number of iterations  
1385 of Algorithm 2, it still does not reach the same performance levels. A line seems to form  
1386 local regions of high probability making it difficult for points to postulate slightly changed  
1387 line coordinates.

### 1388 3.4.2 Two Examples

1389 In the following we show two examples to understand the inference process better. Fig-  
1390 ure 3.5 shows the assignment after a single Gibbs step in Algorithm 1. There is a single line  
1391 that is represented by two clusters. Algorithm 1 does not have merge or split steps to group  
1392 these clusters at once, it thus has to move each data point one by one. By the way, there  
1393 are split-merge algorithms that take these more sophisticated Gibbs steps into account (Jain  
1394 and Neal, 2004).

1395 The example in Fig. 3.6 shows that a single point as an outlier is not a problem for our  
1396 method. A single point might throw off Bayesian linear regression, but because there are  
1397 multiple lines to be estimated in our Infinite Line Mixture Model, this single point is assigned  
1398 its own line.

1399 The extension to more points as outliers would of course require us to postulate a distribution  
1400 for these outlier points as well. A uniform distribution might for example be used in tandem  
1401 with the proposed model. This however would lead to a non-conjugate model and hence  
1402 different inference methods.

**Figure 3.3:** The performance of Algorithm 1 with respect to clustering is measured using the Rand Index, the Adjusted Rand Index, the Mirkin metric, and the Hubert metric. A figure of 1 means perfect clustering for all metrics, except Mirkin's where 0 denotes perfect clustering.

### 1403 3.5 Chapter Conclusions

1404 The Infinite Line Mixture Model that is proposed extends the familiar Bayesian linear regres-  
 1405 sion model to an infinite number of lines using a Dirichlet Process as prior. The model is a  
 1406 full Bayesian method to detect multiple lines. A full Bayesian method, in contrast to ad-hoc  
 1407 methods such as the Hough transform or RANSAC, means optimal inference (Zellner, 1988)  
 1408 given the model and noise definition.

1409 Results in section ?? show high values for difference performance metrics for clustering,  
 1410 such as the Rand Index, the Adjusted Rand Index, and other metrics. The Bayesian model  
 1411 is solved through two types of algorithms. Algorithm 8 iterates over all observations and  
 1412 suffers from slow mixing. The individual updates makes it hard to reassign large number of  
 1413 points at the same time. Algorithm 9 iterates over entire clusters. This allows updates for  
 1414 groups of points leading to much faster mixing. Note, that even optimal inference results  
 1415 in occasional misclassifications. The dataset is generated by a random process. Hence,

**Figure 3.4:** The performance of Algorithm 2 with respect to clustering is measured using the Rand Index, the Adjusted Rand Index, the Mirvin metric, and the Hubert metric. A figure of 1 means perfect clustering for all metrics, except Mirvin's where 0 denotes perfect clustering.

occasionally two lines are generated with almost the same slope and intercept. Points on these lines are impossible to assign to the proper line.

The essential contribution in this chapter is the introduction of a fully Bayesian method to infer lines and there are two ways in which the postulated model can to be extended for full-fledged inference in computer vision as required in robotics. First, the extension of lines in 2D to planes in 3D. This is quite a trivial extension that does not change anything of the model except for the dimension of the data points. Second, somehow a prior needs to be incorporated to limit the lines of infinite length, to line segments. To restrict points on the lines to a uniform distribution of points over a line segment, a symmetric Pareto distribution can be used as prior (for the end points). This would subsequently allow for a hierarchical model in which these end points are in their turn part of more complicated objects. Hence, the Infinite Line Mixture Model is an essential step towards the use of Bayesian methods (and thus properly formulated priors) for robotic computer vision.

**Figure 3.5:** One of the Gibbs steps in the inference of two particular lines. The points are more or less distributed according to the lines, but one line exists out of two large clusters. The line coordinates are visualized by a double circle. The x-coordinate is the y-intercept of the line, the y-coordinate is the slope.

**Figure 3.6:** The assignment of a line to a single point. There are three clusters found, rather than only the obvious two.

# NONPARAMETRIC BAYESIAN SEGMENT ESTIMATION

## Contents

1432

1433

The nonparametric Bayesian model for line estimation (Chapter 3) does not take into account lines that are of finite length. In this chapter, we introduce a Bayesian method to perform inference over such line segments. In this model our prior for the extend of the line segment is a symmetric Pareto distribution. Due to the fact that the prior and likelihood is not a conjugate pair a more general inference method is used, namely Gibbs sampling with auxiliary variables.

1446

1447

1448

1449

1450

The model is using a Normal-Inverse-Gamma and a Pareto prior for an individual line segment (Sect. 4.1). These line segments are generated using a Dirichlet Process (Sect. 4.2). This generative process is used to perform inference using Gibbs sampling over auxiliary variables (Sect. 4.3). The results for inference over line segments are compared with these for lines. (Sect. 4.4). Finally, weak aspects of the current MCMC method are established (Sect. 4.5) which will form the basis for new inference methods in the next chapters.

## 4.1 Pareto Pairs

1451

1452

Lines in a two-dimensional space are mathematical objects that can be described by two parameters. To limit a line to a line segment, four parameters are required. There are

two parametrizations that come to mind. First, a center-point parametrization, in which parameters describe the center of a line segment, the slope of the line through the center, and the size of the line segment. Second, an endpoint parametrization, in which parameters describe the locations of the two endpoints. These parametrizations are equivalent, but generalizations can be intuitive or cumbersome. The generalization to a line segment from a two-dimensional space to a three-dimensional space, requires the endpoints to be positions in a 3D space. The center-point parametrization would require a nonintuitive description of the angles in particular directions. The generalization to squares and rectangles or shapes with many endpoints, might benefit from the center-point parametrization.

There seems to be no statistical description of data points distributed over a line segment that has a conjugate prior form. A line segment itself, however, has a conjugate form! Suppose that we have a prior for the location of endpoints on the x-axis. Given the data we want to update the location of the endpoints. By leaving out the spread of the data over the segment, we can do this using a conjugate Bayesian construction.

The data is distributed according to a symmetric uniform distribution. Hence the likelihood is given by:

$$p(x | a) \sim \mathcal{U}(-a, a) = \begin{cases} \frac{1}{2a} & \text{for } x \leq |a| \\ 0 & \text{otherwise} \end{cases} \quad (4.1)$$

Here the uniform distribution is centered around 0 and extends with size  $a$  in both directions. It is possible to shift the entire distribution with  $b$ . For now, let's continue with one endpoint at  $a$  and one endpoint at  $-a$ .

A prior for the (endpoints of a) symmetric uniform distribution is a symmetric Pareto distribution:

$$p(a) \sim \mathcal{P}_s(\lambda, k) = \begin{cases} \frac{1}{2} k \lambda^k |a|^{-k-1} & |a| \geq \lambda \\ 0 & \text{otherwise} \end{cases} \quad (4.2)$$

The factor  $\frac{1}{2}$  stems from the fact that the symmetric Pareto distribution is now mirrored across the y-axis. Hence, the probability density is half of that of the normal Pareto distribution for the positive x-axis.

If we would just sample from a symmetric Pareto distribution, we can sample multiple times from the positive x-axis. To actually sample endpoints of segments we have to sample pairs of points.

$$p(a, b) \sim \mathcal{P}_p(\lambda_m, \lambda_n, k) \quad (4.3)$$

1482 We can describe this process as first sampling  $a$  and  $b$  from a categorical distribution to  
 1483 decide which one will be the left endpoint and which one the right endpoint. Then we  
 1484 sample the right endpoint from a normal Pareto distribution and the left endpoint from a  
 1485 mirrored Pareto distribution.

1486 The sampling of Pareto pairs is visualized in Fig. 4.1.

**Figure 4.1:** Sampling of Pareto pairs. The parameters are  $\lambda_m = 2$ ,  $\lambda_n = -2$ ,  $k = 5$ , and we have sampled  $N = 1000$  pairs.

1487 The Pareto distribution is a conjugate prior for the uniform distribution, with updated hy-  
 1488 perparameters:

$$p(a \mid D) = \mathcal{P}(c, N + k) \quad (4.4)$$

1489 The data is denoted by  $D = \{x_0, \dots, x_{N-1}\}$ , the parameter  $k$  is adjusted with the number of  
 1490 data points  $N$ , and the parameter  $c$  is the maximum of  $\{m, \lambda\}$  with  $m$  the maximum value  
 1491 in  $D$ .

1492 Given this description for the posterior for a single point, the posterior for a Pareto pair  
 1493 can be found by sampling in parallel from a Pareto distribution  $\mathcal{P}(c_n, N + k_n)$  with  $c_n$  the  
 1494 maximum of the data points  $D$  and  $\lambda_n$ ,  $N$  the number of Pareto pairs, and  $k_n$  the hyperprior  
 1495 for the endpoint at the right. Plus sampling from a Pareto distribution  $\mathcal{P}(c_m, N + k_m)$  with  
 1496  $c_m$  the minimum of the data points  $D$  and  $\lambda_m$ ,  $N$  the same, and  $k_m$  the hyperprior for the  
 1497 endpoint at the left.

1498 If  $k_n \neq -k_m$  the distribution is shifted such that  $k'_n = -k'_m$ . This makes the form of the  
 1499 probability distribution symmetric with respect to the  $y$  axis. In the end the results are  
 1500 shifted back. This transformation makes sense for pairs of points. We do not want the  
 1501 two scale parameters of the Pareto distribution to influence the symmetry of the overall  
 1502 distribution.

1503 Sampling from the Pareto distribution is through inverse transform sampling. By sampling  
 1504 from  $U(0, 1)$  with 1 included, we transform according to  $k/U^{1/a}$ .

1505 Fig. 4.2 shows how the endpoints are updated given the data. An uninformative prior is  
 1506 used. In this case the hyperparameters  $k_n$  and  $k_m$  are set close to 0, thus the data will wash  
 1507 out the prior immediately. Naturally, it is possible to set them quite large. In that case it

**Figure 4.2:** Consider the data uniformly distributed on a line segment and a symmetric Pareto prior for both the endpoints, then we can update the estimate for the endpoints given the data as visualized. Each subfigure shows an adjustment of the endpoints given more data points (1, 3, 10, and 100 data points).

**Figure 4.3:** The Bayesian linear regression model for multiple line segments in plate notation is the same as for the Infinite Line Model. The Dirichlet process is defined at the left with concentration parameter  $\alpha$ . It generates the partitions  $(\pi_1, \dots, \pi_k)$  with assignment parameters  $z_i$  that denote which observation  $w_i$  belongs to which cluster  $k$ . The cluster is summarized through the parameter set  $\theta_k$  and has  $\lambda_0$  as its hyperparameter. The parameter set  $\theta_k$  includes parameters that signify the line itself such as slope and y-intercept, plus the parameters that denote the extend of the segment.

1508 must be noted that the data will never be able to “correct for” this prior. Note also that the  
 1509 maximum and minimum operators are quite sensitive to outliers as well.

## 1510 4.2 Generative Process to Create a Line Segment

1511 To be able to perform inference over a line segment in a two-dimensional space, we’ll have  
 1512 to map somehow these points to a one-dimensional space.

1513 In the case of a line we can sample  $\theta_i$  from a Normal-Inverse-Gamma with hyperparameter  
 1514  $\lambda_{temp}$ . The latter we have in closed form given observations through a single update.

1515 In the case of a line segment there is no known conjugate prior available. Let’s reiterate the  
 1516 Dirichlet Process basis for our nonparametric model:

$$\begin{aligned} G &\sim DP(\alpha, H) \\ \theta_i &| G \sim G \\ w_i &| \theta_i \sim F(\theta_i) \end{aligned} \tag{4.5}$$

1517 Again  $F$  describes the mapping from parameters  $\theta_i$  to observations  $w_i$ . As described, for line  
 1518 segments this mapping is different from that of lines.

$$\begin{aligned} F(\theta_i) &= \mathcal{N}(\mu_i + H(v_i), \Sigma_i) \\ H(v_i) &= \mathcal{N}(v_i, 1)\gamma_i \\ \gamma_i &\sim \mathcal{N}(0, 1) \end{aligned} \tag{4.6}$$

1519 The probability density  $F$  is a Gaussian with a mean that is additively distributed according  
 1520 to another distribution  $H$ . The latter distribution originates from the product of a normal  
 1521 distribution with a value sampled from a normal distribution. Fig. 4.4 shows how points are  
 1522 generated from the described distribution.

**Figure 4.4:** Line segments generated through a Dirichlet Process. The Dirichlet process itself is again the same. But now four parameters are generated. A normal-inverse-Wishart distribution is used to generate the center of the line segment, and an inverse-Wishart distribution to generate one of the endpoints of the line segments (the other end point is mirrored through its center). Points are generated normally over the line segments, with an additional Gaussian component to indicate the deviation from the line segment from the normal-inverse-Wishart.

1523 To generate lines uniformly, only  $\gamma_i$  needs adjustment:

$$\begin{aligned} F(z_i) &= \mathcal{N}(\mu_i + H_i(v_i), \Sigma_i) \\ H(v_i) &= \mathcal{N}(v_i, 1)\gamma_i \\ \gamma_i &\sim \mathcal{U}(-1, 1) \end{aligned} \tag{4.7}$$

1524 Fig. 4.5 displays the adjustment with points generated uniformly over the line segment.

1525 The descriptions in Eq. 4.6 and 4.7 are clearly not conjugate setups. This means that infer-  
 1526 ence over line segments requires more complicated sampling strategies.

### 1527 4.3 Inference over a Line Segment

1528 To perform inference over a line segment our model is not conjugate anymore. This re-  
 1529 quires a sampling algorithm that does not make use of conjugacy. An algorithm that does

**Figure 4.5:** Line segments generated through a Dirichlet Process. Compared to Fig. 4.4 the points are generated uniformly over the line segments: points are not generated outside of the line segments.

1530 not assume conjugacy is described in its general form before (Neal, 2000) (Algorithm 8). The  
 1531 sampling process proposes  $m$  new values for the parameters directly from the hyperparam-  
 1532 eters. These are called auxiliary parameters. Now, to establish to which cluster a certain  
 1533 observation  $w_i$  need to be assigned, the likelihood of each existing and new clusters alike  
 1534 are compared. The weight of an old cluster is defined through the number of data points  
 1535 assigned to it. The weight of a new cluster is defined through  $\alpha/m$ .

1536 After every data item is assigned a cluster, the cluster parameters themselves are updated  
 1537 given the assigned data items. In a conjugate model the sufficient statistics can be updated  
 1538 at once, given such observations. In a nonconjugate model we will need to update  $\theta_j$  by  
 1539 sampling from  $p(\theta_j | y)$ .

**Algorithm 10** Gibbs sampling over auxiliary variables (a  $\theta_i$ )

---

1540 **4.4 Results**

(a) Correctly sampled. Only one outlier to the left.

(b) Incorrectly sampled. The line is recognized as multiple segments.

(c) More or less correct. The segments with fewer observations are recognized poorly.

(d) Completely incorrect. Line segments are chosen to be orthogonal to the lines.

**Figure 4.6:** Bayesian point estimates of the sampling process with varying outcomes.

There is one phenomenon that is very noticeable in Fig. 4.6. Line segments that form a larger line segment are not recognized as such by the inference method.

The results over a larger dataset can be measured with clustering metrics as visualized in Fig. 4.7. The Rand Index, Adjusted Rand Index, and Hubert metrics show all reduced performance compared to line detection where there are no constraints on segment size.

**Figure 4.7:** Segment detection performs much worse than line detection across all three clustering performance indicators. Perfect clustering is indicated by 1.0 for Rand Index, Adjusted Rand Index, and Hubert.

## 4.5 Chapter Conclusions

Segment estimation is a much harder problem than line estimation (Chap. 3). In this chapter we used an advanced method, namely MCMC sampling with auxiliary variables to perform inference over an infinite set of line segments. The parameters for line segments do not have a conjugate description. Metropolis-Hastings has been used to perform inference over the line segments, but the search space is quite large. The auxiliary variable MCMC method is indeed faster than ordinary Metropolis-Hastings thanks to postulating multiple new lines than only one.

However, the segment estimation problem is a challenge for the current inference methods. The target probability density has a lot of modes that each needs to be found and are separated by very low probability regions. In Chapter 5 we will introduce new sampling methods that will cope with these challenges.

1567

The nonparametric Bayesian model for line estimation, the infinite line model (Chapter 3) thanks to its conjugate properties has been solved with moderately straightforward sampling methods. The additional constraints that limit lines to line segments (Chapter 4) reduced convergence of the underlying MCMC sampling method (a Gibbs method with auxiliary variables) to sub-par results.

This chapter introduces a new sampling method called the triadic split-merge sampler.

1574

1575

1576

1577

1578

1579

The class of split-merge samplers, part of MCMC samplers, are introduced (Sect. 5.1). A conventional split-merge sampler, labeled the dyadic split-merge sampler is detailed (Sect. 5.2). The new split-merge sampler, the triadic split-merge sampler is introduced (Sect. 5.3). The results for inference over lines is compared between the conventional and the new sampler (Sect. 5.4). Finally, although this sampler already improves on the state-of-the-art we see in the chapter conclusions (Sect. 5.5) how we further improve the inference procedure, which will be the basis of the next chapter.

1580

## 5.1 The Class of Split-Merge Samplers

1581

1582

We will consider a Dirichlet process as a prior on the distribution over parameters  $G$ . The form of this model is:

$$\begin{aligned}
y_i | \theta_i &\sim F(\theta_i) \\
\theta_i | G &\sim G \\
G &\sim DP(H, \alpha)
\end{aligned} \tag{5.1}$$

## 1583 5.2 Conventional Split-Merge Sampler

1584 The conventional split-merge sampler Jain and Neal (2004) splits a single cluster into two  
 1585 clusters, and merges two clusters into a single cluster. Hence, this split-merge sampler oper-  
 1586 ates on two clusters at each time step, for which reason we will call it a dyadic split-merge  
 1587 sampler in constrast with our approach.

---

### Algorithm 11 Dyadic split-merge sampler

---

```

1: procedure DYADIC SPLIT-MERGE SAMPLER( $c$ )                                ▷ Accepts cluster assignments
    $c$  of length  $N$  (besides Metropolis-Hastings acceptance factors  $a(c', c)$  and a split procedure e.g.
   SIMPLERANDOMSPLIT) and returns a (potentially) updated cluster assignment vector  $c'$ .
2:    $i \sim U(1, N)$                                                          ▷ Sample  $i$  random uniformly over cluster assignments.
3:    $j \sim U(1, N) \cap i$                                                  ▷ Sample  $j$  also random uniformly, but with  $j \neq i$ .
4:    $S_R = \{c_i, c_j\}$                                                      ▷ Sampled clusters  $c_i, c_j$ .
5:    $S_I = \{c_x\}$  with  $c_x \in S_R$  for  $x \in \{1, \dots, N\}$                 ▷ All data in clusters  $c_i, c_j$ .
6:    $S_E = S \cap S_R$                                                      ▷ All data in clusters  $c_i, c_j$  excluding  $S_R$ .
7:    $N_S = \text{unique}(S_R)$ 
8:   if  $N_S = 1$  then                                                     ▷ Case:  $i, j$  belong to the same cluster.
9:      $c_i^{(2)} = c_k$  with  $c_k \notin \{c_1, \dots, c_N\}$                     ▷ Sample new cluster for  $c_i^{(2)}$ .
10:     $c_j^{(2)} = c_j^{(1)}$                                                   ▷ Keep  $c_j$  the same.
11:     $c_e^{(2)} = \text{SPLITPROCEDURE}(S_E, c_i^{(2)}, c_j^{(2)})$                 ▷ After  $c_i^{(2)}, c_j^{(2)}$  assign  $S_E$ .
12:    for all  $m \notin S_I$  do
13:       $c_m^{(2)} = c_m^{(1)}$                                               ▷ Data points in clusters other than  $c_i, c_j$  are not adjusted.
14:    end for
15:     $c' = \{c_i^{(2)}, c_j^{(2)}, c_e^{(2)}, c_m^{(2)}\}$ 
16:     $a = a_{\text{split}}(c', c)$  according to Eq. 5.3                        ▷ MH acceptance for a split.
17:  else                                                                 ▷ Case:  $i, j$  belong to different clusters  $c_i \neq c_j$  ( $N_S = 2$ ).
18:    for all  $q \in S_I$  do
19:       $c_q^{(1)} = c_j^{(2)}$                                               ▷ Assign all data points in  $c_i$  and  $c_j$  to  $c_j$ .
20:    end for
21:    for all  $m \notin S_I$  do
22:       $c_m^{(1)} = c_m^{(2)}$                                               ▷ Data points in clusters other than  $c_i, c_j$  are not adjusted.
23:    end for
24:     $c' = \{c_q^{(1)}, c_m^{(1)}\}$ 
25:     $a = a_{\text{merge}}(c', c)$  according to Eq. 5.10                      ▷ MH acceptance for a merge.
26:  end if
27:   $u \sim U(0, 1)$                                                          ▷ Sample  $u$  between 0 or 1 uniformly.
28:  if  $a < u$  then
29:     $c' = c$                                                              ▷ Reject  $c'$  by setting it to  $c$ 
30:  end if
31:  return  $c'$ , the (updated) cluster assignment vector:  $c \rightarrow c'$ .
32: end procedure

```

---

1588 In algorithm 11 the notation  $c_i^{(2)}$  is used to signify that the cluster assignment  $c_i$  has 2 clusters  
 1589 under consideration. In the dyadic algorithm we could have used  $c_i^{merge}$  and  $c_i^{split}$ , however  
 1590 in the triadic algorithm (see algorithm 14) with multiple split and merge operations the  
 1591 latter notation would become confusing.

---

**Algorithm 12** Simple random split
 

---

```

1: procedure SIMPLERANDOMSPLIT( $S, c_0, c_1$ )  $\triangleright$  Accepts unassigned set  $S$  and cluster indices  $c_0, c_1$ ,
   returns cluster assignment  $c'_m$ .
2:   for all  $m \in S$  do
3:      $c'_m \sim \text{Cat}(c_0, c_1)$  with equiprobable  $p(c_0) = p(c_1) = \frac{1}{2}$ .
4:   end for
5:   return  $c'_m$ , the cluster assignment for  $S$ .
6: end procedure
  
```

---

1592 The dyadic split-merge sampler in Algorithm 11 samples two distinct data items. If the data  
 1593 items belong to the same cluster a split step is attempted. If the data items belong to different  
 1594 clusters a merge step is attempted. The split procedure itself is the so-called simple random  
 1595 split (Algorithm 12) that assigns data items with the same probability to one of the parts of  
 1596 the splitted cluster without consideration for data fit.

### 1597 5.2.1 Acceptance for the Split Step

1598 The acceptance ratio contains the Metropolis ratio to step from  $c$  to  $c'$ :

$$\frac{P(c')L(c'|y)}{P(c)L(c|y)} \quad (5.2)$$

1599 Additionally, the Hastings correction is applied because of the asymmetry of the proposal  
 1600 distribution in the form of  $q(c|c')/q(c'|c)$ :

$$a_{split}(c^{(2)}, c^{(1)}) = \min \left[ 1, \frac{q(c^{(1)}|c^{(2)})}{q(c^{(2)}|c^{(1)})} \frac{P(c^{(2)})}{P(c^{(1)})} \frac{L(c^{(2)}|y)}{L(c^{(1)}|y)} \right] \quad (5.3)$$

1601 The notation  $c^{(2)}$  is used to indicate that the cluster index vector is referencing 2 unique  
 1602 clusters (in this case after the split step).

1603 The prior distribution is represented by a Chinese Restaurant Process with concentration  
 1604 parameter  $\alpha$  and no discount factor. Data not yet assigned is assigned with probability  
 1605  $\alpha/(n + \alpha)$  to a new cluster and with probability  $n_c/(n + \alpha)$  to an existing cluster  $c$ . Here  $n$   
 1606 are the total number of assigned data points,  $n_c$  are the number of data points assigned to  
 1607 cluster  $c$ . There are  $D$  clusters. Hence, the prior over clusters:

$$P(c) = \frac{\Gamma(\alpha)}{\Gamma(\alpha + n)} \alpha^D \prod_{c_l} \Gamma(n_{c_l}) = \alpha^D \frac{\prod_{c_l} (n_{c_l} - 1)!}{\prod_{k=1}^n (\alpha + k - 1)} \quad (5.4)$$

1608 In the prior distribution ratio before and after the split step many of the factors drop out.  
 1609 There is one factor  $\alpha$  remaining and the number of data points in the splitted cluster is part

of the equation. There is no dependency on other clusters or the total number of data points and we can simplify the formula using the beta function  $B(a, b)$ :

$$\frac{P(c^{(2)})}{P(c^{(1)})} = \alpha \frac{(n_{c_i^{(2)}} - 1)!(n_{c_j^{(2)}} - 1)!}{(n_{c_i^{(1)}} - 1)!} = \alpha B(n_{c_i^{(2)}}, n_{c_j^{(2)}}) \quad (5.5)$$

The likelihood can be written as:

$$L(c|y) = \prod_{c=1}^D \prod_{k:c_k=c} p(y_k|\phi) \quad (5.6)$$

Here we assume no conjugacy between  $F(y_k, \phi)$  and prior distribution  $H(\phi)$  and hence write  $p(y_k|\phi)$  rather than the conjugate construction  $\int F(y_k, \phi) dH_{k,c}(\phi)$  (see Dahl (2005)). The likelihood ratio becomes:

$$\frac{L(c^{(2)}|y)}{L(c^{(1)}|y)} = \frac{\prod_{k:c_k^{(2)}=c_i^{(2)}} p(y_k|\phi) \prod_{k:c_k^{(2)}=c_j^{(2)}} p(y_k|\phi)}{\prod_{k:c_k^{(1)}=c_i^{(1)}} p(y_k|\phi)} \quad (5.7)$$

The split step determines the probability of a particular split. Given that already two data points are assigned to distinct clusters, only the remaining ones have to be assigned with equal probability to  $c_i^{(2)}$  and  $c_j^{(2)}$ :

$$q(c^{(2)}|c^{(1)}) = \left(\frac{1}{2}\right)^{-2+n_{c_i^{(2)}}+n_{c_j^{(2)}}} = \left(\frac{1}{2}\right)^{-2+n_{c_i^{(1)}}} \quad (5.8)$$

The probability of the reverse of the split operation is exactly 1. There is only one way in which a single cluster could have risen from a split cluster, hence:

$$\frac{q(c^{(1)}|c^{(2)})}{q(c^{(2)}|c^{(1)})} = \frac{1}{\left(\frac{1}{2}\right)^{n_{c_i^{(2)}}+n_{c_j^{(2)}}-2}} = 2^{-2+n_{c_i^{(1)}}} \quad (5.9)$$

### 5.2.2 Acceptance for the Merge Step

Acceptance of a merge step consists of the same components as that of the split step.

$$a_{merge}(c^{(1)}, c^{(2)}) = \min \left[ 1, \frac{q(c^{(2)}|c^{(1)}) P(c^{(1)}) L(c^{(1)}|y)}{q(c^{(1)}|c^{(2)}) P(c^{(2)}) L(c^{(2)}|y)} \right] \quad (5.10)$$

$$\frac{P(c^{(1)})}{P(c^{(2)})} = \alpha^{-1} \frac{(n_{c_i^{(1)}} - 1)!}{(n_{c_i^{(2)}} - 1)!(n_{c_j^{(2)}} - 1)!} = \frac{1}{\alpha B(n_{c_i^{(2)}}, n_{c_j^{(2)}})} \quad (5.11)$$

$$\frac{L(c^{(1)}|y)}{L(c^{(2)}|y)} = \frac{\prod_{k:c_k^{(1)}=c_i^{(1)}} p(y_k|\phi)}{\prod_{k:c_k^{(2)}=c_i^{(2)}} p(y_k|\phi) \prod_{k:c_k^{(2)}=c_j^{(2)}} p(y_k|\phi)} \quad (5.12)$$

1625

$$\frac{q(c^{(2)}|c^{(1)})}{q(c^{(1)}|c^{(2)})} = \left(\frac{1}{2}\right)^{-2+n_{c_i^{(1)}}} = 2^{2-n_{c_i^{(1)}}} \quad (5.13)$$

1626 The ratios of the merge step are the inverse of the ratios of the split step.

1627 **5.2.3 Sequentially-Allocated Merge-Split Sampler**

1628 A variant on the conventional split-merge sampler is the Sequentially Allocated Merge-Split<sup>1</sup>  
 1629 (SAMS) sampler Dahl (2003). The simple random split procedure of Algorithm 12 is re-  
 1630 placed by a procedure that sequentially assigns observations to clusters rather than splitting  
 1631 the data random uniformly over the splitted clusters.

**Algorithm 13** Sequentially Allocated Merge-Split

---

```

1: procedure SAMS( $S, c_0, c_1$ )    ▷ Accepts unassigned set  $S$ , cluster indices  $c_i$ , and  $p(y_k|\theta_{c_i})$  with
    $i = 0, 1$ , returns cluster assignment  $c'_m$ .
2:    $T = \text{random\_shuffle}(S)$ 
3:   for all  $m \in T$  do
4:      $p(c_m = c_0 | c_0, c_1, \theta_{c_0}, \theta_{c_1}) = \frac{N_0 p(y_k | \theta_0)}{N_0 p(y_k | \theta_0) + N_1 p(y_k | \theta_1)}$ 
5:      $p(c_m = c_1 | c_0, c_1, \theta_{c_0}, \theta_{c_1}) = 1 - p(c_m = c_0 | c_0, c_1, \theta_{c_0}, \theta_{c_1})$ 
6:      $c'_m \sim p(c_m | c_0, c_1, \theta_{c_0}, \theta_{c_1})$ 
7:   end for
8:   return  $c'_m$ , the cluster assignment for  $S$ .
9: end procedure

```

---

1632 In contrast to the simple random split, observations  $y_k$  are used in the SAMS to obtain cluster  
 1633 assignments that correspond with the data rather than cluster assignments independent of  
 1634 the data.

1635 **5.3 Triadic split-merge sampler**

1636 The triadic split-merge sampler uses up to three clusters for a split or merge step (Fig. 5.1).

---

<sup>1</sup>In the naming of split-merge or merge-split samplers, the order of merge split does not bear any significance.

**Figure 5.1:** Right: dyadic MCMC picks two data items  $i, j$  random uniformly. If both are in the same cluster a split towards two clusters is attempted. If both are in distinct clusters a merge towards one cluster is attempted. Left: triadic MCMC picks three data items  $i, j, k$  random uniformly. If all three are in the same cluster a split towards two clusters is attempted. If the three items are in two clusters either a split into three (with probability  $1 - \beta$ ) or a merge into a single cluster (with probability  $\beta$ ) is attempted. If the three data items are in three distinct clusters a merge is attempted. There are no direct transitions from a single cluster to three clusters or the other way around.

1637 The intuition behind the triadic split-merge sampler is twofold:

- 1638 ○ In the dyadic sampler there is a large asymmetry between split and merge steps. There  
 1639 is only one way in which two clusters can be merged into one single cluster, while there  
 1640 are many ways in which one single cluster can be split into two clusters. This asym-  
 1641 metry is reduced by transitioning between two and three clusters. This is a straight-  
 1642 forward improvement in balancing split and merge steps (for alternatives, see Wang  
 1643 and Russell (2015)).
- 1644 ○ In practical optimization problems it might be useful to form a third cluster out of  
 1645 subsets of two other clusters. The dyadic MCMC sampler requires immediate steps in  
 1646 which (1) one of these clusters is split into two, (2) the other is split into two, and  
 1647 (3) the two new clusters are merged. This means that (a) mixing and hence conver-  
 1648 gence will be slow and (b) the intermediate steps might have very low probability and  
 1649 function as an unnecessary barrier between high probable states.

1650 Sampling random uniformly for three unique items is implemented through a random shuf-  
 1651 fle algorithm, in particular the modern version of the Fisher-Yates shuffle introduced by  
 1652 Durstenfeld Durstenfeld (1964) and picking the first three items.

### 1653 5.3.1 Acceptance for the Split Step

1654 In the triadic split-merge sampler there are two splitting steps. It is possible to split according  
 1655 to the dyadic split-merge sampler. However, given two clusters there are (split) jumps to  
 1656 three states as well as (merge) jumps to single states again. To account for this asymmetry  
 1657 another Hastings correction is applied to establish detailed balance.

$$a_{split}(c^{(2)}, c^{(1)}) = \min \left[ 1, \frac{r(c^{(1)}|c^{(2)}) q(c^{(1)}|c^{(2)}) P(c^{(2)}) L(c^{(2)}|y)}{r(c^{(2)}|c^{(1)}) q(c^{(2)}|c^{(1)}) P(c^{(1)}) L(c^{(1)}|y)} \right] \quad (5.14)$$

**Algorithm 14** Triadic split-merge sampler

---

```

1: procedure TRIADIC SPLIT-MERGE SAMPLER( $c$ )                                ▷ Accepts
   cluster assignments  $c$  of length  $N$  (besides Metropolis-Hastings acceptance factors  $a(c', c)$  and a
   split procedure) and returns a (potentially) updated cluster assignment vector  $c'$ .
2:    $i \sim U(1, N)$                                 ▷ Sample  $i$  random uniformly over cluster assignments.
3:    $j \sim U(1, N) \cap i$                             ▷ Sample  $j$  also random uniformly, but with  $j \neq i$ .
4:    $k \sim U(1, N) \cap \{i, j\}$                         ▷ Sample  $k$  random uniformly, but with  $k \neq j, k \neq i$ .
5:    $S_R = \{c_i, c_j, c_k\}$                                 ▷ Sampled clusters  $c_i, c_j, c_k$ .
6:    $S_I = \{c_x\}$  with  $c_x \in S_R$  for  $x \in \{1, \dots, N\}$         ▷ All data in clusters  $c_i, c_j, c_k$ .
7:    $S_E = S_I \cap S_R$                                 ▷ All data in clusters  $c_i, c_j, c_k$  excluding  $S_R$ .
8:    $N_S = \text{unique}(S_R)$ 
9:    $u \sim U(0, 1)$                                 ▷ Sample  $u$  between 0 or 1 uniformly.
10:  if  $N_S = 1$  then                                ▷ Case:  $i, j, k$  belong to the same cluster.
11:    return  $c' = \text{DYADIC SPLIT-MERGE SAMPLER}(c)$ 
12:  else if  $N_S = 2$  and  $u < \beta$  then                ▷ Case: a cluster with one item and one with two items and
    $u < \beta$ .
13:    return  $c' = \text{DYADIC SPLIT-MERGE SAMPLER}(c)$ 
14:  else if  $N_S = 2$  and  $u \geq \beta$  then                ▷ Case: a cluster with one item and one with two items and
    $u \geq \beta$ .
15:     $c_i^{(3)} = c_k$  with  $c_k \notin \{c_1, \dots, c_N\}$         ▷ Sample new cluster for  $c_i^{(3)}$ .
16:     $c_j^{(3)} = c_j^{(2)}$                                 ▷ Keep  $c_j$  the same.
17:     $c_e^{(3)} = \text{SPLITPROCEDURE}(S_E, c_i^{(3)}, c_j^{(3)})$         ▷ After  $c_i^{(3)}, c_j^{(3)}$  assign  $S_E$ .
18:    for all  $m \notin S_I$  do
19:       $c_m^{(3)} = c_m^{(2)}$                                 ▷ Data points in clusters other than  $c_i, c_j$  are not adjusted.
20:    end for
21:     $c' = \{c_i^{(3)}, c_j^{(3)}, c_e^{(3)}, c_m^{(3)}\}$ 
22:     $a = a_{\text{split}}(c', c)$  according to Eq. 5.14        ▷ MH acceptance for a split.
23:  else                                ▷ Case:  $i, j, k$  belong to three different clusters  $c_i \neq c_j \neq c_k$  ( $N_S = 3$ ).
24:     $S_L = S_I \cap \{c_i^{(3)}, c_j^{(3)}\}$                 ▷ Data in clusters  $c_i, c_j, c_k$  except for  $i$  and  $j$  itself.
25:     $\{c_i^{(2)}, c_j^{(2)}\} = \text{SAMS}(S_L, c_i^{(3)}, c_j^{(3)})$         ▷ Assign data points in  $c_i, c_j, c_k$  to  $c_i, c_j$ .
26:    for all  $m \notin S_L$  do
27:       $c_m^{(2)} = c_m^{(3)}$                                 ▷ Data points in clusters other than  $S_L$  are not adjusted.
28:    end for
29:     $c' = \{c_i^{(2)}, c_j^{(2)}, c_m^{(2)}\}$ 
30:     $a = a_{\text{merge}}(c', c)$  according to Eq. 5.21        ▷ MH acceptance for a merge.
31:  end if
32:   $u \sim U(0, 1)$                                 ▷ Sample  $u$  between 0 or 1 uniformly.
33:  if  $a < u$  then
34:     $c' = c$                                 ▷ Reject  $c'$  by setting it to  $c$ 
35:  end if
36:  return  $c'$ , the (updated) cluster assignment vector:  $c \rightarrow c'$ .
37: end procedure

```

---

1658 Here we have one additional term compared to the split step from one cluster to two clusters:

$$\frac{r(c^{(1)}|c^{(2)})}{r(c^{(2)}|c^{(1)})} = \frac{\beta}{1} \quad (5.15)$$

1659 The parameter  $\beta$  is free to control, as long as  $0 < \beta < 1$  (to maintain ergodicity). The  
1660 transition from two states to three states is another split step:

$$a_{split}(c^{(3)}, c^{(2)}) = \min \left[ 1, \frac{r(c^{(2)}|c^{(3)})}{r(c^{(3)}|c^{(2)})} \frac{q(c^{(2)}|c^{(3)})}{q(c^{(3)}|c^{(2)})} \frac{P(c^{(3)})}{P(c^{(2)})} \frac{L(c^{(3)}|y)}{L(c^{(2)}|y)} \right] \quad (5.16)$$

1661 The fraction with  $r$ :

$$\frac{r(c^{(2)}|c^{(3)})}{r(c^{(3)}|c^{(2)})} = \frac{1}{1 - \beta} \quad (5.17)$$

1662 The fraction with  $q$  uses the total number of data points  $n_c$  in the clusters:

$$\frac{q(c^{(2)}|c^{(3)})}{q(c^{(3)}|c^{(2)})} = \frac{\left(\frac{1}{2}\right)^{n_c-2}}{\left(\frac{1}{3}\right)^{n_c-3}} = (3^{n_c-3})(2^{2-n_c}) = \left(\frac{3}{2}\right)^{n_c} \frac{2^2}{3^3} \quad (5.18)$$

1663 To move from 2 clusters to 3 clusters the probability is a  $1/3$  for each cluster index in vector  
1664  $c$  (except for the three data items already selected randomly, hence  $n_c - 3$ ). To move back,  
1665 the probability is a  $1/2$  and there are only two data items randomly assigned beforehand.  
1666 The fraction with  $P$  uses the number of data points in each of the clusters before and after  
1667 the step:

$$\frac{P(c^{(3)})}{P(c^{(2)})} = \alpha \frac{(n_{c_i^{(3)}} - 1)!(n_{c_j^{(3)}} - 1)!(n_{c_k^{(3)}} - 1)!}{(n_{c_i^{(2)}} - 1)!(n_{c_j^{(2)}} - 1)!} = \alpha \frac{B(n_{c_i^{(3)}}, n_{c_j^{(3)}}, n_{c_k^{(3)}})}{B(n_{c_i^{(2)}}, n_{c_j^{(2)}})} \quad (5.19)$$

1668 Here we introduced a generalized Beta function  $B(a, b, c) = \Gamma(a)\Gamma(b)\Gamma(c)/\Gamma(a + b + c)$  with  
1669  $\Gamma(x) = (x - 1)!$  the Gamma function. The likelihood ratio becomes:

$$\frac{L(c^{(3)}|y)}{L(c^{(2)}|y)} = \frac{\prod_{m:c_m^{(3)}=c_i^{(3)}} P(y_m|\phi) \prod_{m:c_m^{(3)}=c_j^{(3)}} P(y_m|\phi) \prod_{m:c_m^{(3)}=c_k^{(3)}} P(y_m|\phi)}{\prod_{m:c_m^{(2)}=c_i^{(2)}} P(y_m|\phi) \prod_{m:c_m^{(2)}=c_j^{(2)}} P(y_m|\phi)} \quad (5.20)$$

### 1670 5.3.2 Acceptance for the Merge Step

1671 The merge step from two to one cluster is analogous to the split step:

$$a_{merge}(c^{(1)}, c^{(2)}) = \min \left[ 1, \frac{r(c^{(2)}|c^{(1)})}{r(c^{(1)}|c^{(2)})} \frac{q(c^{(2)}|c^{(1)})}{q(c^{(1)}|c^{(2)})} \frac{P(c^{(1)})}{P(c^{(2)})} \frac{L(c^{(1)}|y)}{L(c^{(2)}|y)} \right] \quad (5.21)$$

1672 The merge step from three clusters to two clusters is:

$$a_{merge}(c^{(2)}, c^{(3)}) = \min \left[ 1, \frac{r(c^{(3)}|c^{(2)})}{r(c^{(2)}|c^{(3)})} \frac{q(c^{(3)}|c^{(2)})}{q(c^{(2)}|c^{(3)})} \frac{P(c^{(2)})}{P(c^{(3)})} \frac{L(c^{(2)}|y)}{L(c^{(3)}|y)} \right] \quad (5.22)$$

1673 Note that all the fractions in Eq. 5.22 are the reverse of the fractions in Eq. 5.16. Inverting  
1674 Eq. 5.17–5.20 will be left to the reader.

One additional issue we have to consider. When merging three clusters into two we can (1) distribute the data over all three clusters or (2) alternatively, keep the data in two clusters assigned to these clusters and only distribute the data in the third cluster over the other two clusters. The second and alternative option however would introduce unnecessary asymmetry with the merge step. In other words, Eq. 5.23 is not the inverse of Eq. 5.18. In contrast, the equation is similar to splitting one cluster across two as in Eq. 5.9:

$$\frac{q_{alt}(c^{(3)}|c^{(2)})}{q_{alt}(c^{(2)}|c^{(3)})} = 2^{-2+n_c} \quad (5.23)$$

Hence the first option is entertained and the  $q$ -fraction is exactly the inverse of Eq. 5.18.

Another choice has been made, namely to exclude direct operations between a single cluster and three clusters. This is because factors like:

$$\frac{P(c^{(3)})}{P(c^{(1)})} = \alpha^2 \frac{(n_{c_i^{(3)}} - 1)!(n_{c_j^{(3)}} - 1)!(n_{c_k^{(3)}} - 1)!}{(n_{c_i^{(1)}} - 1)!} \quad (5.24)$$

become very small and although compensated by a large  $q$  fraction, remain further away from an acceptance factor of 1. Note that by the ability to split a single cluster into two and then into three, there is no ergodic argument to introduce also the immediate step.

## 5.4 Results

The problem we use to test our sampler is a well-known problem in computer vision, namely that of the inference of line parameters (slope and intercept) given data points. Rather than ordinary linear regression, in computer vision there is a mixture of lines that have to be estimated. Moreover, the number of lines is not known beforehand. To solve this problem we use the Dirichlet process mixture (Eq. 5.1) with a normal distribution  $N(0, \sigma_0)$  to generate the line parameters and a likelihood function that defines points to be uniformly distributed across a line of length 20 and deviating from the line according to a normal distribution  $N(0, \sigma_1)$ .

**Figure 5.2:** Two examples of fitting a mixture of lines to data items scattered over a two-dimensional space. The lines drawn are inferred using one of the methods in this chapter. The lines are not the ground truth, but are meant to demonstrate the typical errors made by fitting methods. Note for example that there are mistakes in both the assignment of points to lines as well as the line parameters (slope and intercept).

#### 1696 5.4.1 Implementation

1697 The sampler is open-source<sup>2</sup> implemented in C++ which means that (a) it is computationally  
 1698 fast, (b) it can be run on embedded devices if a cross-compiler is available and the Eigen3  
 1699 library is ported. Note, that due to the fact that the simulator uses a lot of random numbers  
 1700 the system should use a modern compiler (g++-6 or newer) and should have enough entropy  
 1701 available<sup>3</sup>. Rather than a random scan, the implementation uses a fixed scan as advocated  
 1702 in the literature MacEachern (2007).

1703 To speed up the sampler most calculations are done in log-space. Consider  $v = u + 1$ . The  
 1704 ratio with probabilities (Eq. 5.5 and 5.19) becomes:

$$\log \frac{P(c^{(v)})}{P(c^{(u)})} = \log(\alpha) + \sum_i \log \Gamma(n_{c_i^{(v)}}) - \sum_i \log \Gamma(n_{c_i^{(u)}}) \quad (5.25)$$

1705 The fraction with  $q(\cdot)$  (Eq. 5.9 and 5.18) becomes:

$$\log \frac{q(c^{(v-1)}|c^{(v)})}{q(c^{(v)}|c^{(v-1)})} = (v - n_c - 1) \log(v - 1) - (v - n_c) \log(v) \quad (5.26)$$

1706 The fraction with  $r$  becomes for example (Eq. 5.17):

$$\log \frac{r(c^{(2)}|c^{(3)})}{r(c^{(3)}|c^{(2)})} = -\log(1 - \beta) \quad (5.27)$$

<sup>2</sup>Code can be found at <https://code.annevanrossum.nl/noparama>.

<sup>3</sup>On Linux this can be checked in `/proc/sys/kernel/random/entropy_avail`.

1707 The log-probability to calculate the likelihood given by a multivariate Normal distribution is  
 1708 well-known.

## 1709 5.4.2 Comparison

1710 The Triadic sampler using SAMS is compared with the Jain-Neal Dyadic sampler using SAMS  
 1711 and an auxiliary variable sampler with  $m = 3$  (see algorithm 8 in Neal (2000)).

Method	Purity	Rand Index	Adjusted Rand Index
Dyadic sampler	0.80960	0.80580	0.56382
Auxiliary variables	0.87235	0.85879	0.68224
Triadic sampler	0.86405	0.87188	0.71067

**Table 5.1:** The purity, rand index, and adjusted rand index establishing the quality of the clustering method. The closer the values to one, the better the method performed. The purity metric assigns high values to clusters that do not have data points from other clusters (but does not penalize the number of clusters). The rand index computes similarity between clusters taking false negatives and false positives into account. The adjusted rand index accounts for chance. The adjusted rand index is most useful in our comparison.

1712 In Table 5.1 the line estimation problem is compared for the dyadic sampler, an auxiliary  
 1713 variables sampler, and the proposed triadic sampler. The simulation is run with  $\beta = 0.1$  so  
 1714 that a significant number of steps are tried between two and three clusters (rather than only  
 1715 between one and two clusters).

**Figure 5.3:** The same results as in Table 5.1, but visualized in a violin plot. The distribution over metric values are displayed in a vertical fashion. From left to right the distribution shifts to one, signifying better clustering performance.

1716 In Fig. 5.3 the different metrics are visualized in the form of violin plots. The improvement  
 1717 in clustering is especially visible with the adjusted rand index.

## 1718 5.5 Chapter Conclusions

1719 A new split-merge sampler has been introduced, implemented, and applied to the computer  
1720 vision problem of line estimation. The sampler outperforms existing samplers, such as the  
1721 ordinary (dyadic) split-merge sampler Jain and Neal (2004) and auxiliary variable sampler  
1722 Neal (2000).

1723 Although the proposed split-merge sampler is able to mix considerably faster through a mix-  
1724 ture model, it does not use global jumps directly based on the data. It is reasonable to suggest  
1725 that MCMC methods benefit from combining the local jumps with global jumps, for example  
1726 by a mixture of the local Metropolis-Hastings sampler with a Metropolized independence  
1727 sampler Jampani et al. (2015). We will introduce such a sampler in chapter 6.

# ADVERSARIALLY TRAINED MCMC KERNELS

**Contents** To use MCMC for volumetric inference it is necessary to be able to accelerate the algorithms even further. Volumetric objects exhibit more structure, which is reflected by symmetry.

**Outline** We describe MCMC methods that cope with symmetric objects.

## 6.1 Data-Driven Inference

There are three aspects we would like to address in our inference engine.

The first aspect aims to have structure within our inference engine. The proposal distribution in a Markov chain, although moderately complex in the previous chapter, does not have much knowledge about the model. An artificial border is maintained that does not allow the inference engine to have knowledge about the model. The purpose of this is never articulated in particular. However, it is logical from a separation of concern. Such an inference engine (1) does not need to receive any information about the model and (2) is guaranteed to be general in the sense that it is not tailored to a particular model. This is nicely articulated by Tran et al. (2017) from which we quote.

“Many existing probabilistic programming languages treat the inference engine as a black box, abstracted away from the model. These cannot capture probabilistic inferences that reuse the model’s representation - a key idea in recent advances in variational inference, generative adversarial networks, and also in more classic inference.”

The second aspect concerns the data. In MCMC the position for the chain is driven by (1) the prior, (2) the prior and the likelihood, (3) a sequence of priors and likelihood, (4) a

sequence of priors, likelihood and proposal distributions, basically anything, except for the data itself. Data-driven approaches would namely destroy the convergence of the Markov chain. To start an MCMC sampler in a data-driven manner and continue in a data-oblivious manner is a possible solution (Zhang and Perez-Cruz, 2017). Even better, it is possible to use a Metropolized independence sampler Jampani et al. (2015). Such a sampler samples independently from the previous state and uses global information. However, to work well its proposal distribution needs to match the target distribution quite well. Although, when combined with a local sampler, it might be sufficient to just be able to match the modes of the target distribution well.

The third aspect concerns the way we build our MCMC engine. The split-merge sampler of the previous chapter has been meticulously designed. If we admit a data-driven approach, we might as well adjust our MCMC engine using training samples. Note, that this training will be across a set of line, box, or scenes mixtures. The MCMC engine will not be able to learn just the parameters of a particular visual object. It will learn how to jump around (optionally, adaptively) from one visual object to the next or from one cluster configuration to the next. In other words, it will be able to teach itself to become a Triadic Split-Merge sampler if that happens to be a good engine. Is it possible to constrain the search through MCMC kernels such that its result is always converging in an MCMC sense? If we aim to learn the transition operator of our Markov chains, there is new literature that makes use of deep nets.

## 6.2 Learning the Transition Operator

There are multiple methods that can be used in a generative setting. We will discuss the three most prominent ones: (1) generative adversarial networks, (2) variational autoencoders, and (3) infusion training. This is far from an extensive categorization, worth studying are variational walkback (Goyal et al., 2017), stacked generative adversarial networks (Huang et al., 2016), generative latent optimization (Bojanowski et al., 2017), deep learning through the use of non-equilibrium thermodynamics (Sohl-Dickstein et al., 2015), denoising autoencoders, or generative stochastic networks, to name just a few.

### 6.2.1 Adversarial Training

Adversarial training has been extensively studied since the article on generative adversarial networks by Goodfellow et al. (2014). A particular adversarial setup for training an MCMC has been suggested as well (Song et al., 2017). The generator samples from a Markov chain. A discriminator subsequently needs to judge if its incoming data comes from the generator or if it is sampled from the actual data set. To start the process, the generator can run the chain from the model as well as from the data.

**Figure 6.1:** Left:  $p_z(z)$  is a (prior) random distribution that generates random variables  $z$ . Middle: the generator  $G$  maps the random variables  $z$  to simulated data points  $x'$ . Right: the discriminator  $D(x, x')$  compares the simulated data  $x'$  with the real data  $x$ . The generator tries to generate samples in such way that the discriminator has difficulties distinguishing the simulated from the real data.

### 1788 6.2.2 Variational Autoencoders

1789 Variational autoencoders (Kingma and Welling, 2013; Rezende et al., 2014) are ordinary  
 1790 autoencoders with additional constraints on the latent variables. The latent variables in  
 1791 autoencoder parlance are called the code. In a variational autoencoder the latent variables  
 1792 are forced to approximately describe a unit Gaussian distribution. The autoencoder is trained  
 1793 using a loss function that is composed out of (1) a generative loss, a mean squared error  
 1794 that measures how accurately the network reconstructs its input, and (2) a latent loss, a KL-  
 1795 divergence that measures how closely the latent variables match a unit Gaussian. To optimize  
 1796 the KL divergence a reparameterization trick is applied. The encoder does not generate a  
 1797 vector with real values, but generates a vector with means and standard deviations instead.

**Figure 6.2:** Left:  $q_F(h|x)$  maps the data  $x$  to (hidden) random variables  $h$ . Middle:  $p_G(x|h)$  maps the hidden random variables to reconstructed data  $x'$ . Right:  $L(x, x')$  measures the similarity between  $x$  and  $x'$ .

### 1798 6.2.3 Infusion Training

1799 The transition operator can also be learned directly through infusion training. In infusion  
 1800 training we gradually adjust totally unstructured noise to a target distribution as well. In this  
 1801 method a particular data point is ‘infused’ into the Markov chain to bias the model sampling  
 1802 to move towards this particular data point (and not another). In contrast to a generative  
 1803 loss that is a mean squared error, this promises to have less blurry reconstructions.

### 1804 6.3 Volumetric Models

1805 In image processing autoencoders have been used for 2D shape recognition. To apply the  
1806 same type of models to 3D point clouds, these point clouds are represented through voxels.  
1807 The application of data-driven deep learning techniques, be it autoencoders, generative ad-  
1808 versarial networks, or adversarial autoencoders promises similar good results in these 3D  
1809 settings than in the current computer vision tasks.

1810 The 3D ShapeNet model (Wu et al., 2015) exists of 3D voxel input that is piped through  
1811 several stages with an increasing number of filters. The used voxel representation is a bi-  
1812 nary tensor. It assigns a value of 1 to each voxel that is inside the 3D object mesh and a  
1813 value 0 to each voxel outside the mesh (empty space). The voxel sizes are fixed as well as  
1814 the grid size (in this particular model the grid exists of 30x30x30 voxels). The inference  
1815 model is a Deep Belief Network (DBN). Convolution operators, in the form of filters over  
1816 small neighbourhoods, are used to reduce the number of model parameters (30x30x30 fully  
1817 connected would be really many weights). The DBN is used in a supervised setting where  
1818 shapes are trained with object labels. The model subsequently learns to generate shapes  
1819 given an object label.

1820 An unsupervised method in the form of a convolutional (volumetric) autoencoder (Sharma  
1821 et al., 2016) has been applied to the same type of data. This (denoising) autoencoder,  
1822 coined VConv-DAE maps from an entire voxel grid to another voxel grid. This work uses a  
1823 combination of standard techniques, a dropout layer, a deconvolution layer, ReLu as well as  
1824 sigmoid activation, but it is not in particular tailored to 3D point clouds.

1825 Other representations than voxels are used. For example collections of 2D views and trans-  
1826 formation parameters (Dosovitskiy et al., 2017). The most interesting are methods that  
1827 work with raw data, the point cloud themselves. This alleviate the need to process the data  
1828 and does not inadvertently increase the data dimensions, for example by artificially introduce  
1829 voxels where there is no object present.

1830 PointNet (?) directly operates on point clouds. To handle the input as a set of points (un-  
1831 ordered), it uses a symmetric function over  $n$  input vectors and outputs a vector that is  
1832 invariant to the input order. Typically sum and multiplication operators are such symmetric  
1833 functions. After input and feature transforms by multi-layer perceptrons, a max pooling op-  
1834 erator is used to map the input to a global feature. In the ModelNet40 shape classification  
1835 benchmark there are more than 12000 CAD models from 40 object categories. PointNet  
1836 achieves state of the art results compared to volumetric methods for a fraction of the com-  
1837 putational costs.

1838 Point clouds are also directly used in so-called deep kd-networks (Klokov and Lempitsky,  
1839 2017). A kd-tree is constructed by recursively picking the coordinate axis with the largest  
1840 range of point coordinates and splitting the set of points into two subsets of equal size.  
1841 These subsets are recursed into successively. The recursion stops at a particular level, depth  
1842  $D$ . The kd-networks are purported to outperform for example PointNet amongst other model  
1843 architectures.

1844 A deep permutation equivariant (for semisupervised learning) and permutation invariant  
1845 (for supervised learning) network has also been directly applied to point clouds (Ravanbakhsh  
1846 et al., 2016). It does not reach the ModelNet40 accuracy levels from PointNet or the kd-  
1847 networks though.

1848 PointNet++ Qi et al. (2017) introduces hierarchical structure to PointNet. This fits better  
1849 non-uniform point distributions and seems to surpass kd-nets again on the ModelNet40 task.

1850

1851

## RECOMMENDER ENGINE

### Contents

1853

1854

1855

The described nonparametric Bayesian models (Chapter 3, 4, 5, and 6) are not limited to computer vision tasks. This chapter describes a recommender engine in which groups of runners are extracted from data collected from social media.

### Outline

1857

1858

1859

1860

1861

We (1) introduce the form of the data at hand, (2) describe a multi-modal Von Mises-Uniform distribution to model the individual runners, (3) use a Dirichlet Process prior to group people, (4) use the previously described MCMC methods to perform inference, (5) show the results on an artificial and real-world data set, and (6) discuss ways with which the model can be expanded.

## 7.1 Application

1862

The data of people exercising can be considered binary (someone is either exercising or not in a particular timeslot). We do have however more information available. We know how often people have been exercising in a timeslot. This data has the form as visualized in Table 7.1.

**Table 7.1:** Example of the type of data about the timing of exercising. A person is represented by row, her preferences by column. There is not a predefined number of users or groups of users.

1867 The first row defines the time of day, starting at midnight till the last timeslot from 23.00 till  
 1868 00.00. In this particular case it shows that nobody is running from midnight to four o'clock  
 1869 in the morning, understandably so.

## 1870 7.2 Model of Individuals

### 1871 7.2.1 Multi-modal Normal-Uniform Distribution Model

1872 We first postulate the likelihood function for the moments at which people exercise through  
 1873 the day as defined in Eq. 7.1.

$$f(x|\theta) = w_0 \mathcal{U}(a, b) + \sum_{i=1}^2 w_i \mathcal{N}(\mu_i, \sigma_i) \quad (7.1)$$

1874 The likelihood (Eq. 7.1) is built up out of three probability density functions: one Uniform dis-  
 1875 tribution  $\mathcal{U}(a, b)$  with  $a$  and  $b$  as parameters and two Normal distributions  $\mathcal{N}(\mu_i, \sigma_i)$  with  
 1876 mean  $\mu_i$  and  $\sigma_i$ . The distributions are weighted by the factors  $w_0, w_1, w_2$ . The collection of  
 1877 parameters for the likelihood function is referred to by  $\theta = \{a, b, \mu_1, \sigma_1, \mu_2, \sigma_2, w_0, w_1, w_2\}$ .

1878 This probability density function  $f(x|\theta)$  will have the form as in Fig. 7.1. The uniform  
 1879 distribution generates values here between 00:00 and 24:00. There are on top of that the  
 1880 two Normal distributions that form peaks at certain moments during the day.

**Figure 7.1:** The likelihood function for the moments at which people decide to exercise during the day. On the horizontal axis time, on the vertical axis the frequency of exercising.

1881 There is something noticable in Fig. 7.1, namely that the 24 hours of a day cause the Nor-  
 1882 mal distribution to be cut off. Especially in Fig. 7.1 (a) there should be some considerable  
 1883 likelihood of running in the wee hours of the morning between 00:00 and 01:00.

## 1884 7.2.2 Multi-modal Von-Mises-Uniform Distribution Model

1885 There are several options to define a distribution over a limited range  $T$ . A so-called wrapped  
 1886 distribution is a distribution defined over the unity circle. By just multiplying it with  $T/(2\pi i)$   
 1887 it can be used to define a probability density function over a day ( $T = 24$ ).

$$f(x|\theta) = w_0 \mathcal{U}(a, b) + \sum_{i=1}^2 w_i \mathcal{VM}(\mu_i, \kappa_i) \quad (7.2)$$

1888 The likelihood (Eq. 7.2) is again built up out of three probability density functions: one  
 1889 Uniform distribution  $\mathcal{U}(a, b)$  with  $a$  and  $b$  as parameters and two Von Mises distributions  
 1890  $\mathcal{VM}(\mu_i, \kappa_i)$  with mean  $\mu_i$  and  $\kappa_i$ . The parameters  $\mu_i$  will be scaled and shifted with  $[a, b]$  so  
 1891 all variables within this range fall on the unity circle. The parameter  $\kappa_i$  plays the same role as  
 1892  $\sigma_i$  for the Normal distribution. The distributions are weighted by the factors  $w_0, w_1, w_2$ . The  
 1893 collection of parameters for the likelihood function is referred to by  $\theta = \{a, b, \mu_1, \kappa_1, \mu_2, \kappa_2, w_0, w_1, w_2\}$ .

**Figure 7.2:** The improved likelihood function for the moments at which people decide to exercise during the day using the Von Mises distribution. On the horizontal axis time, on the vertical axis the frequency of exercising.

The likelihood with Von Mises distributions rather than Normal distributions is visualized in Fig. 7.2. The Von Mises distributions capture behavior in deviations from a standard exercise time. It does not take into account structured deviations, for example running late from work every Thursday, or weekends, or a person either running in the morning or in the evening, but never both at the same day.

### 7.2.3 Hyperparameters

The parameters  $\theta$  for each user  $j$  are either fixed or generated from prior distributions. The hyperparameters  $a$  and  $b$  for the Uniform distribution are set to 0 and 24. People can run potentially any time of the day. The hyperparameters  $\mu_i, \kappa_i$  for the Von Mises distributions are generated from a Uniform-Exponential distribution (Eq. 7.3). The Uniform distribution reflects the fact that if people run on regular times, this time can be any time of the day. The Exponential distribution defines a prior on how much people deviate from such a regular time to exercise.

$$\begin{aligned} f(\mu_i|a, b) &= \mathcal{U}(a, b) \\ f(\kappa_i|\lambda) &= \mathcal{E}(\lambda) \end{aligned} \tag{7.3}$$

The Uniform distribution generates  $\mu_i$  between  $a$  and  $b$ . The parameter  $\kappa_i$  is generated from an Exponential distribution with hyperparameter  $\lambda$ . If  $\lambda$  is set to be small ( $< 0.5$ ) we have a high likelihood that  $\kappa$  can be large and we have pronounced peaks. In contrary, if  $\lambda$  is set to be large, the Von Mises distribution likely approaches the Uniform distribution due to a higher chance of sampling a small value for  $\kappa$ .

The weights we sample from a normalized product of a zero-deflated Bernoulli distribution and a Dirichlet distribution (Eq. 7.4).

$$f(w_i|p, \alpha_i) = \mathcal{B}(p)\mathcal{D}(\alpha_i)/Z \quad (7.4)$$

The Bernoulli distribution samples zeros and ones with probability of  $p = 0.5$ , leading to 3-vectors like 001, 101, etc. The distribution is corrected in such way that the chance to sample 000 is zero. The Bernoulli distribution only gives weights  $w_i = 0$  or  $w_i = 1$ , hence it is multiplied with a Dirichlet distribution. The Dirichlet samples a 3-vector with weights between zero and one where the weights  $\sum_i w_i = 1$ . A symmetric Dirichlet distribution with  $\alpha = 1$  is similar to the Uniform distribution over the simplex. It is set slightly more towards favoring particular distributions with  $\alpha_i = 1/3$  (we assume that people sample one or two distributions, and rarely from all three). The product with the zero-deflated Bernoulli distribution is made up to sum up to one again by normalizing the result.

We can combine Eq. 7.3 and Eq. 7.4 in Eq. 7.5:

$$\theta \sim \mathcal{U}(a, b)\mathcal{E}(\lambda)\mathcal{B}(p)\mathcal{D}(\alpha_i)/Z \quad (7.5)$$

To sample the parameters  $\theta$  this is the base distribution we will encounter in the next section 7.3.

## 7.3 Model of Groups

Each person's exercise schedule is represented by a Von-Mises-Uniform distribution. People that are similar do have exercise schedules that can be represented by the same Von-Mises-Uniform distribution. To group similar schedules we define a nonparametric discrete distribution over a potentially infinite number of groups with each person assigned to a group.

A Dirichlet Process (Eq. 7.6) is a distribution over distributions that can be used as a prior for such a nonparametric discrete distribution.

$$DP(\alpha, H) \quad (7.6)$$

The Dirichlet Process has (1) a hyperparameter  $\alpha$ , which defines the likelihood that there are many clusters versus few clusters (although it doesn't say anything about its actual count), and (2) a base distribution  $H$ , the distribution that generates  $\theta$  (Eq.7.5).

## 7.4 Inference

The implementation of the model makes use of Gibbs sampling with auxiliary variables Jain and Neal (2007).

Details on this algorithm can be found in Jain and Neal (2007) and previous work of the authors van Rossum et al. (2016a,b).

**Algorithm 15** Gibbs sampling over auxiliary variables

---

```

1: procedure GIBBS ALGORITHM WITH AUXILIARY VARIABLES( $w, \lambda_0, \alpha$ )      ▷ Accepts schedule  $w$ ,
   hyperparameters  $\lambda_0, \alpha$ , number of auxiliary variables  $m$ , and returns  $k$  groups
2:   for all  $t = 1 : T$  do
3:     for all  $i = 1 : N$  do
4:       for all  $j = 1 : m$  do
5:          $\theta_j \sim H(\lambda_0)$                                           ▷ Sample  $\theta_j$  from base distribution  $H$  in Eq. 7.5
6:       end for
7:       for all  $j = 1 : K + m, j \neq i$  do
8:          $L_j = \text{likelihood}(w_i, \theta_j)$       ▷ Update likelihood for all theta (except  $\theta_i$ ) given  $w_i$ 
9:       end for
10:       $P_{-i=1:K} = b \sum_{-i} L_{-i}$                                           ▷ Calculate probability of existing cluster
11:       $P_{-i=K:K+m} = b\alpha/mL_mL_{-i}$       ▷ Calculate probability of new cluster
12:       $\theta_i = \theta_j$  according to above  $P_{-i}$       ▷ Sample  $\theta_i$  accord. to above prob
13:      Remove unused clusters
14:    end for
15:    for all  $j = 1 : K$  do
16:       $\theta_j \sim p(\theta_j | y)$                                           ▷ Update  $\theta_j$ 
17:    end for
18:  end for
19:  return summary on  $\theta_k$  for  $k$  groups of runners
20: end procedure

```

---

**7.5 Results**

The algorithm is run first on an artificial dataset of which we know the ground truth (Sect. 7.5.1) and next on the real-world dataset from Twitter (Sect. 7.5.2).

**7.5.1 Artificial Dataset**

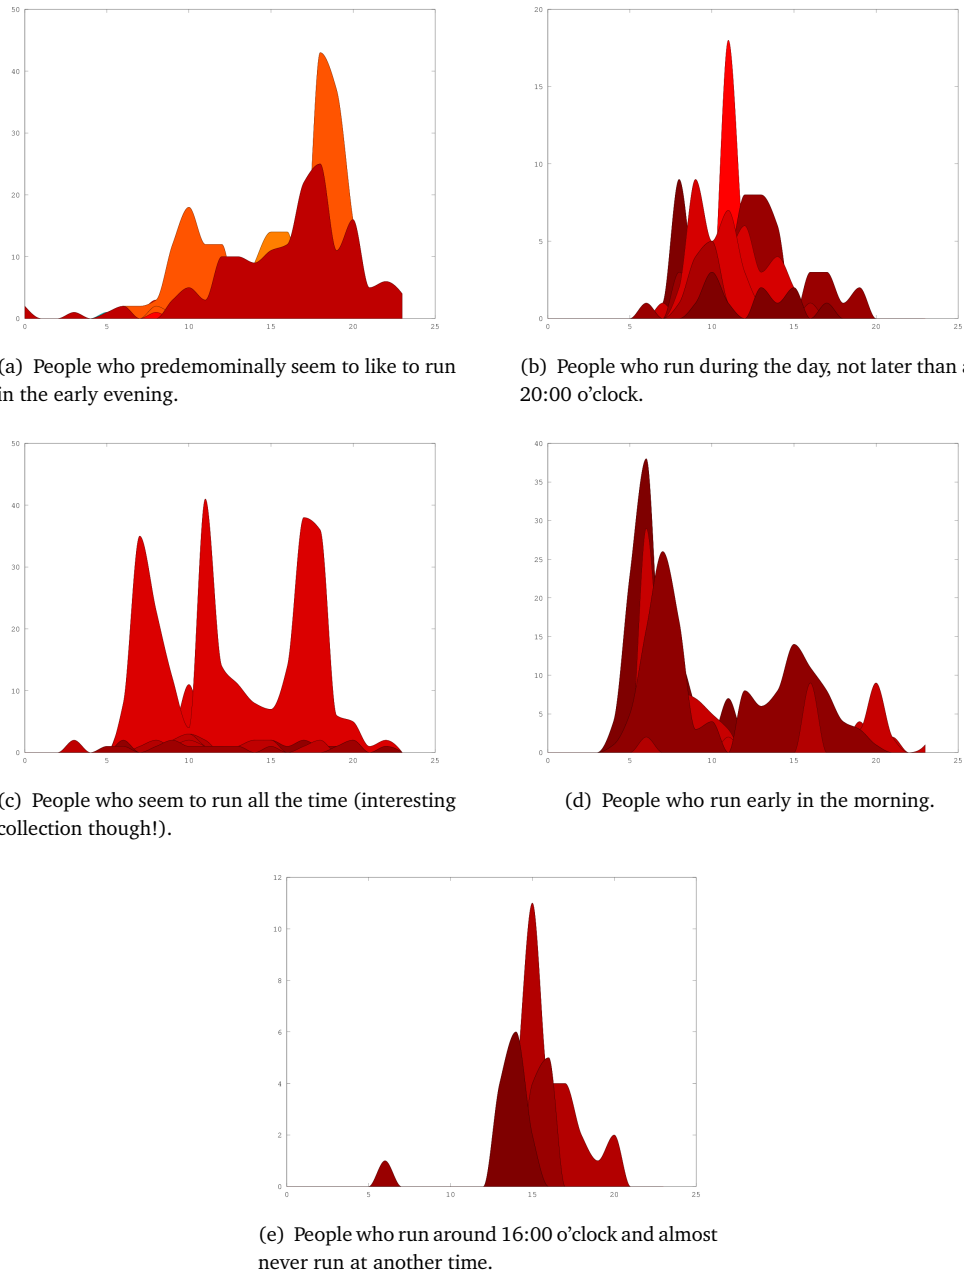

The algorithm has been used on a self-generated dataset (generated from the probability density function as in Fig. 7.2). In this case we have the ground truth that establishes which exercise schedule comes from which probability density function. Using this ground truth we can calculate how often our algorithm makes a mistake, grouping a person with people that belong to another group. The results with this dataset are perfect (Rand Index equal to one: perfect clustering). The results are of the form of Table 7.2 (except by a permutation of indices), hence are not shown (the indices have no intrinsic meaning).

**Table 7.2:** Top row: A sequence of cluster indices indicates the ground truth. Each cluster index represents a multi-modal Von-Mises-Uniform distribution with different parameters  $\theta$ . Bottom row: A sequence of cluster indices that are the result of the described algorithm. Each cluster index represents again a multi-modal Von-Mises distribution. Errors would be represented by an inconsistent mapping from the top row to the bottom row.

## 1952 7.5.2 Real-world Dataset

1953 The results when we actually use the collected Twitter dataset can be best visualized (Fig. 7.3).  
 1954 This dataset consists of around 4000 moments at which people decide to run. The dataset  
 1955 is subsequently filtered on regulars, people that at least have run a few times.

**Figure 7.3:** After running the algorithm, the above figures show the different categories of runners that have been found.

1956 The results in Fig. 7.3 show that there is a categorization of people indeed. After the al-  
 1957 gorithm has done its work it is possible to assign a certain label in a post-hoc manner, e.g.  
 1958 “People who run around 16:00 o'clock and almost never run at another time.”.

## 1959 7.6 Discussion

1960 The postulated model allows to reason about groups of people performing exercising, with-  
1961 out predefining what these groups constitute apart from very general characteristics such  
1962 as that there might be preferred times of day to exercise. A Dirichlet process is used as a  
1963 nonparametric Bayesian model in which both the number of groups and the assignment of  
1964 people exercising are learnt from the data.

1965 There are several directions in which this research can be extended. First, more data would  
1966 be very helpful. Only a limited number of people are posting consistently their training  
1967 data online. Tapping into the data of current fitness promoting companies would allow the  
1968 model to wash out the prior a bit more and adjust to the data. Second, we also collected  
1969 weather data over this time period and also expect the day of the week to have significant  
1970 influence. When there will be more data available these are logically dimensions to include  
1971 in the dataset. Third, it would be interesting to study if people relate to the group of people  
1972 they have been categorized with. Can this help or support their exercise regime?

1973

## PROBABILISTIC CONCEPTS

**TODO:** What follows down here is old and has to be adapted to the measure-theoretic realizations.

Let us introduce the notation of expectation for random variable  $X$ :

$$E_p[X] = \sum_i^k p(X = x_i) x_i \quad (\text{A.1})$$

For the continuous case, if  $f_X(x)$  is a properly defined probability density function, the expected value becomes:

$$E_f[X] = \int_{-\infty}^{\infty} x f_X(x) dx \quad (\text{A.2})$$

From the context it can be seen that the object  $X$  at the left is a different object than  $x$  at the right. The former is random variable (a one-dimensional function, an (in)finite vector), the latter is a value of a random variable (a scalar). The term  $dx$  is a measure, in this case it assigns volume to *subsets of random variables values*. A proper notation would incorporate this aspect, but not much will be gained by creating such complex notations.

Let us also introduce the conditional probability:

$$p(X|Y) = \frac{p(X, Y)}{p(Y)} \quad (\text{A.3})$$

Suppose  $X$  is a discrete random variable, then the object  $p(X)$  is a vector of finite size  $k$ ,  $p(Y)$  is a vector of finite size  $l$ , and  $p(X|Y)$  as well as  $p(X, Y)$  are matrices of size  $k \times l$ . A conditional probability hence ‘divides’ a matrix by a vector. It is a proper measure if  $p(Y) \neq 0$  (for all values of - or events in -  $Y$ ).

2289 In for example importance sampling (Sect. ??), the expectation is taken over a function of  
 2290 a random variable. A function, if measurable, can be taken the expectation over using the  
 2291 so-called law of the unconscious statistician:

$$E_f[g(X)] = \int_{-\infty}^{\infty} g(x)f_X(x)dx \quad (\text{A.4})$$

2292 Here  $g(X)$  is a general measurable function, and not restricted to a probability density func-  
 2293 tion.

2294 The notation above is an indefinite integral. We can approach this integral by Monte Carlo  
 2295 integration (Sect. ??).

$$E_f[g(X)] = \frac{1}{k} \sum_{i=1}^k g(x_i) \quad \text{with} \quad x_i \sim f_X(x) \quad (\text{A.5})$$

2296 Rather than summing over  $f_X(x_i)$ , we now sample  $x_i \sim f_X(x)$ .

## 2297 **A.1 Common Inequalities**

### 2298 **A.1.1 Markov's Inequality**

2299 Markov's inequality comes up with an upper bound for the probability that an non-negative  
 2300 random variable  $X$  exceeds some constant positive threshold  $a$ .

$$p(X \geq a) \leq \frac{E[X]}{a} \quad (\text{A.6})$$

2301 The proof in classical probability theory uses an indicator variable:

$$aI(X \geq a) \leq X \quad (\text{A.7})$$

2302 Here  $I(X \geq a) = 1$  if the event  $X \geq a$  occurs, setting the left-hand side to  $a$  (which is of  
 2303 course smaller than  $X$ ). And  $I(X \geq a) = 0$  on the event  $X < a$ , which is naturally smaller  
 2304 than the non-negative  $X$ .

2305 Expectations obey the inequality: if  $(X \leq Y)$ , then  $E[X] \leq E[Y]$ , hence:

$$E[aI(X \geq a)] \leq E[X] \quad (\text{A.8})$$

2306 And because expectations add up linearly:

$$E[aI(X \geq a)] = aE[I(X \geq a)] = a(1 \cdot p(X \geq a) + 0 \cdot p(X < a)) = a \cdot p(X \geq a) \quad (\text{A.9})$$

2307 So, we have Markov's inequality combining Eq. A.8 and A.9:

$$a \cdot p(X \geq a) \leq E[X] \quad (\text{A.10})$$

### 2308 A.1.2 Chebyshev's Inequality

2309 Now, Chebyshev's inequality defines in a similar way (Chebyshev was a teacher of Markov<sup>1</sup>)  
 2310 an upper bound on the deviation from the mean for a random variable. Recall the definition  
 2311 of the variance of  $X$  and assume it is finite:

$$\text{Var}(X) = E[(X - E[X])^2] = \sigma^2 \quad (\text{A.11})$$

2312 Consider now the random variable  $(X - E[X])^2$  and constant  $a = (\sigma k)^2$  and write down  
 2313 Markov's inequality:

$$p((X - E[X])^2 \geq (\sigma k)^2) \leq \frac{E[(X - E[X])^2]}{(\sigma k)^2} \quad (\text{A.12})$$

2314 Taking the square root of the inequality at the left, and using the definition of  $\sigma^2$  at the  
 2315 right, leads to:

$$p(|X - E[X]| \geq \sigma k) \leq \frac{1}{k^2} \quad (\text{A.13})$$

### 2316 A.1.3 Weak Law of Large Numbers

2317 Chebyshev's inequality can be used to prove the weak law of large numbers. Given that we  
 2318 have a series of random variables, all with the same finite expectation,  $E[X_i] = \mu$ , then this  
 2319 law states that the sample average  $\bar{X} = \frac{1}{n}(X_1 + \dots + X_n)$  converges in probability towards  
 2320 the expected value:

$$\bar{X} \xrightarrow{P} \mu \quad \text{for} \quad n \rightarrow \infty \quad (\text{A.14})$$

2321 We can use the independence assumption between variables  $X_i$  to write down the variance  
 2322 and expectation of  $\bar{X}$ :

$$\text{Var}(\bar{X}) = \text{Var}\left(\frac{1}{n}(X_1 + \dots + X_n)\right) = \frac{1}{n^2} \text{Var}(X_1 + \dots + X_n) = \frac{\sigma^2}{n} E[\bar{X}] = \mu \quad (\text{A.15})$$

---

<sup>1</sup>There were many mathematically gifted Markov's. This is Andrey Andreyevich Markov Sr., known from the Markov chains and Markov processes. Jr. is known from Markov's principle, Markov's rule and the Markov algorithm.

2323 And now we can apply Chebyshev's inequality on  $\bar{X}$ :

$$p(|\bar{X} - \mu| \geq \epsilon) \leq \frac{\sigma^2}{n\epsilon^2} \quad (\text{A.16})$$

2324 Convergence in probability towards  $X$  is the case if for all  $\epsilon$ :

$$\lim_{n \rightarrow \infty} p(|\bar{X} - X| \geq \epsilon) = 0 \quad (\text{A.17})$$

2325 This is the case for  $n \rightarrow \infty$  indeed.

#### 2326 **A.1.4 Strong Law of Large Numbers**

2327 The strong law incorporates the weak law. Rather than convergence *in probability*, it states  
2328 convergence *almost surely* towards the expected value.

$$\bar{X} \xrightarrow{a.s.} \mu \quad \text{for} \quad n \rightarrow \infty \quad (\text{A.18})$$

2329 The strong law states that with probability 1, for any  $\epsilon > 0$ , the inequality  $|X - \mu| < \epsilon$   
2330 holds for large enough  $n$ . The weak law states only that the average  $\bar{X}$  is likely near  $\mu$ , but  
2331  $|X - \mu| \geq \epsilon$  can still happen, even for large  $n$ .

#### 2332 **A.1.5 Common Distributions**

2333 One of the probability distributions that is interesting to us is the beta-distribution. A normal  
2334 distribution might be a reasonable prior for a continuous variable such as human heights in  
2335 a population. If this variable however is itself a probability, a reasonable prior is the beta-  
2336 distribution. The beta-distribution can be described as:

$$f(x, \alpha, \beta) = \frac{1}{B(\alpha, \beta)} x^{\alpha-1} (1-x)^{\beta-1} = \frac{\Gamma(\alpha + \beta)}{\Gamma(\alpha)\Gamma(\beta)} x^{\alpha-1} (1-x)^{\beta-1} \quad (\text{A.19})$$

2337 Here  $B$  is the beta function and  $\Gamma$  is the gamma function, the continuous extension of the  
2338 factorial function:  $\Gamma(n) = (n-1)!$ . Naturally, there are many of such extensions. The  
2339 gamma function extends the factorial in a specific sense. It obeys the recurrence relation  
2340  $f(x+1) = xf(x)$  with  $f(1) = 1$ . Its description is defined with an improper integral:

$$\Gamma(t) = \int_0^\infty x^{t-1} e^{-x} dx \quad (\text{A.20})$$

2341 The expected value of a random variable  $X$  with a beta-distribution:

**Figure A.1:** The beta-distribution with different parameters. The x-axis is the quantity modelled, for example a ratio between wins and losses in a soccer season. The y-axis is the corresponding unnormalized density function. Setting  $\alpha = 1$  shows a monotonically decreasing density function. Having a variable  $\alpha$  allows probability mass to shift to the end.

$$E_f[X] = \int_0^1 x f(x, \alpha, \beta) dx = \int_0^1 \frac{\Gamma(\alpha + \beta)}{\Gamma(\alpha)\Gamma(\beta)} x^\alpha (1-x)^{\beta-1} dx = \frac{\alpha}{\alpha + \beta} \quad (\text{A.21})$$

2342 Let us illustrate the effects of the parameters of the beta-distribution.

2343 The stick-breaking presentation shows that a Dirichlet process consists of beta processes with  
 2344  $\alpha = 1$ . The Pitman-Yor process has  $\alpha$  left variable. Informally, the location where the stick  
 2345 will be broken (iteratively) for the Dirichlet process is ‘quite close to the beginning’ with high  
 2346 probability. In the case  $\alpha$  becomes larger, the breaking can also occur likely at the end of the  
 2347 stick. This means for breaking a stick, say 20 times, the distribution of stick lengths for the  
 2348 Pitman-Yor process has a much larger support. The difference between the large and small  
 2349 sticks is much larger.

## DIRICHLET-MULTINOMIAL

There is confusion in the literature with respect to the Dirichlet-multinomial. There are three ways to interpret this.

### B.1 Categorical Distribution

Often, the Dirichlet-multinomial is actually not a compound Dirichlet and a multinomial, but a compound Dirichlet and **categorical** distribution:

$$p(z|\theta) = \prod_i \theta_i^{z_i} \quad (\text{B.1})$$

This means that this is about only one categorical variable, not a set. The notation of above would for dice assign the vector  $[1, 0, 0, 0, 0, 0]$  to the face with one pip,  $[0, 1, 0, 0, 0, 0]$  to the face with two pips, etc. Naturally, this means that  $\sum_i z_i = 1$ .

This gets rid off the  $\frac{n!}{\prod_i z_i!}$  factor and leads to the much shorter:

$$p(z|\theta)p(\theta|\alpha) = \frac{1}{B(\alpha)} \prod_i \theta_i^{z_i + \alpha_i - 1} \quad (\text{B.2})$$

To subsequently derive at the Dirichlet-multinomial, you'll have to integrate over:

$$\int p(z|\theta)p(\theta|\alpha)d\theta = \frac{1}{B(\alpha)} \int \prod_i \theta_i^{z_i + \alpha_i - 1} d\theta \quad (\text{B.3})$$

Now, the Dirichlet didn't come from nowhere... The factor  $B(\alpha)$  is a normalization factor:

$$p(\theta|\alpha) = \frac{1}{B(\alpha)} \prod_i \theta_i^{\alpha_i-1} = \frac{\prod_i \theta_i^{\alpha_i-1}}{\int_{\Delta^n} \prod_i \theta_i^{\alpha_i-1} d\theta} \quad (\text{B.4})$$

2363 with  $\int_{\Delta^n}$  corresponding to the condition  $\sum_i \theta_i = 1$ .

2364 In other words, the multivariate Beta function is actually this integral directly from the def-  
2365 inition:

$$\int_{\Delta^n} \prod_i \theta_i^{\alpha_i-1} d\theta = B(\alpha) \quad (\text{B.5})$$

2366 And hence the integral:

$$\int \prod_i \theta_i^{z_i+\alpha_i-1} d\theta = B(\alpha + z) \quad (\text{B.6})$$

2367 Hence:

$$\int p(z|\theta)p(\theta|\alpha)d\theta = \frac{B(\alpha + z)}{B(\alpha)} \quad (\text{B.7})$$

2368 Or to end up with something commonly stated as the Dirichlet-multinomial:

$$\int p(z|\theta)p(\theta|\alpha)d\theta = \frac{\prod_i \Gamma(\alpha_i + z_i)}{\Gamma(\sum_i (\alpha_i + z_i))} \frac{\Gamma(\sum_i \alpha_i)}{\prod_i \Gamma(\alpha_i)} \quad (\text{B.8})$$

2369 Collecting terms:

$$\int p(z|\theta)p(\theta|\alpha)d\theta = \frac{\Gamma(\sum_i \alpha_i)}{\Gamma(\sum_i \alpha_i + \sum_i z_i)} \prod_i \frac{\Gamma(\alpha_i + z_i)}{\Gamma(\alpha_i)} \quad (\text{B.9})$$

2370 Note, however that we run  $i$  here over the entries in our categorical variable  $z$  represented  
2371 as a vector! This is very different from a multinomial distribution over a set of variables!

## 2372 **B.2 Multinomial Distribution**

2373 In case of an actual multinomial distribution, counts of  $z$ , let's write them  $n(z)$  are actually  
2374 the topic of consideration, not  $z$  itself.

$$p(z|\theta) = \frac{(\sum_k n(z_k))!}{\prod_k (n(z_k))!} \prod_k \theta_k^{n(z_k)} \quad (\text{B.10})$$

2375 We now run over  $k$  unique variables, not over a vectorized categorical variable.

2376 Of course, we can know again multiply with a Dirichlet distribution and the derivation is  
 2377 along the lines as described before. The result:

$$\int p(z|\theta)p(\theta|\alpha)d\theta = \frac{(\sum_k n(z_k))!}{\prod_k (n(z_k)!) } \frac{\Gamma(\sum_k \alpha_k)}{\Gamma(\sum_k \alpha_k + \sum_k n(z_k))} \prod_k \frac{\Gamma(\alpha_k + n(z_k))}{\Gamma(\alpha_k)} \quad (\text{B.11})$$

2378 This might not be pretty, but it is the actual full Dirichlet-multinomial.

### 2379 B.3 N Categorical Distributions

2380 The third option, and this is meant most times is the distribution of a **sequence** of categorical  
 2381 variables. Recall that the multinomial assigns probabilities to the **number** of extracted balls  
 2382 (in an experiment getting n balls out of a bag with k ball types). A sequence of categorical  
 2383 variables assigns a probability to a **sequence** and has a form without the normalization  
 2384 factor:

$$p(z|\theta) = \prod_k \theta_k^{z_k} \quad (\text{B.12})$$

2385 Here  $k$  runs over the categories. We can now follow the derivation as with the single cate-  
 2386 gorical variable.

## GIBBS SAMPLING

2387

2388

2389 Notation:

$$\int dF(x) = F(x) \quad (\text{C.1})$$

2390 A mixture model:

$$L(x) = \int dF(x) \mu(x) \quad (\text{C.2})$$

2391 If we have a particular form of  $F(x)$ , namely it admits a decomposition of a sum of individual  
 2392 values  $x_i$ :

$$F(x) = \sum_i \delta_{x_i} = \delta(x = x_0) + \delta(x = x_1) + \dots \quad (\text{C.3})$$

2393 Then our mixture model can be written as:

$$L(x) = \int dF(x) \mu(x) = \sum_i \mu(x_i) \quad (\text{C.4})$$

2394 Let  $x_0 = 3$ ,  $x_1 = 4$ ,  $\mu(x) = x^2$ , then  $L(x) = 3^2 + 4^2 = 25$ .2395 Walker with  $P = F$ ,  $\mu(x) = N(y|\theta)$ ,  $i = j$  and giving each  $\theta_j$  a weight  $\omega_j$ :

$$f_P(y) = \int dP(\theta) N(y|\theta) \quad P = \sum_j \omega_j \delta_{\theta_j} \quad (\text{C.5})$$

2396 Then:

$$f_{\omega,j}(y) = \sum_j \omega_j N(y|\theta_j) \quad (\text{C.6})$$

2397 The likelihood:

$$L(w | \alpha, \lambda_0) = p(\phi | \alpha) \prod_{i=0}^{N-1} \int p(w_i | \theta_i, \phi) dG_0(\theta_i) \quad (\text{C.7})$$

2398 Here the index runs over all data points  $w_i$ . Each data point corresponds to a line with  
 2399 parameters  $\theta_i$ . Here the parameters  $\theta_i$  and  $\theta_j$  for data point  $w_i$  and  $w_j$  can be the same and  
 2400 thus reflect the same line. The index for  $\theta$  runs over the  $N$  data points, not over the  $K$  lines.

2401 The distribution  $G_0$  does have hyperparameters  $\lambda_0$ .

2402 We can also group all data points that belong to the same line  $k$  together by reordering the  
 2403 product terms:

$$L(w | \alpha, \lambda_0) = p(\phi | \alpha) \prod_k \prod_{i:z_i=k} \int p(w_i | \theta_i, \phi) dG_0(\theta_i) \quad (\text{C.8})$$

2404 Here the factors that belong to line  $k$  are multiplied. The index still runs over the data points.

2405 It is also possible not to limit the second product to only the data points  $i$  that are assigned  
 2406 to line  $k$ .

$$L(w | \alpha, \lambda_0) = p(\phi | \alpha) \prod_k \prod_i p(z_i | \phi) \int p(w_i | \theta_i, \phi) dG_0(\theta_i) \quad (\text{C.9})$$

2407 Now, we are gonna introduce the stick-breaking sum, which turns our integral into a discrete  
 2408 sum.

2409  $G = \sum_l p_l \delta_{Z_l}$  with  $Z_l$  iid from  $G_0$  and  $p_l$  defined as a product of beta distributions.

$$L(w | \alpha, \lambda_0) = p(\phi | \alpha) \sum_k \prod_i p(z_i | \phi) p(w_i | \theta_k) p(\theta_k | \lambda_0) \quad (\text{C.10})$$

2410 The first term at the right hand side,  $p(\phi | \alpha)$ , generates the partition  $\phi$  by the Dirichlet  
 2411 process with concentration parameter  $\alpha$ . The second term  $p(z_i | \phi)$  defines indices  $z_0, \dots, z_N$   
 2412 to link observations  $w_0, \dots, w_N$  with the parameters  $\theta_0, \dots, \theta_K$ . The probability  $p(w_i | \theta_k)$   
 2413 corresponds to the likelihood equations 3.10 and 3.11 with  $w_i$  the tuple of  $x_i$  and  $y_i$  and  
 2414  $\theta_k$  the line parameters  $\sigma_k^2$  and  $\beta_k$ . The probability  $p(\theta_k | \lambda_0)$  corresponds to the prior from  
 2415 equation 3.14. The parameters  $\theta_k$  (that is,  $\sigma_k^2$  and  $\beta_k$ ) are generated from hyperparameters  
 2416  $\lambda_0$ . The hyperparameters  $\lambda_0 = \{\mu_0, \Lambda_0, a, b\}$  are the parameters from the Normal-Inverse-  
 2417 Gamma prior.

2418 The Dirichlet process can be used as a mixture model (Antoniak, 1974; Escobar and West,  
 2419 1995; MacEachern and Müller, 1998) in which it generates (non-unique) parameters that  
 2420 subsequently generate observations:

$$\begin{aligned} G &\sim DP(\alpha, G_0) \\ \theta_i &| G \sim G \\ w_i &| \theta_i \sim F(\theta_i) \end{aligned} \quad (C.11)$$

2421 Here  $F$  describes the mapping from parameters  $\theta_i$  to observations  $w_i$ . It is possible to inte-  
 2422 grate over  $G$  and sample the parameters directly from the base distribution  $G_0$ .

2423 It is possible to integrate over  $G$  and get a description in the form of conditionals over the  
 2424 parameters (Blackwell and MacQueen, 1973):

$$\theta_{n+1} | \theta_1 \dots \theta_{n-1} \sim \frac{1}{\alpha + n} (\alpha G_0 + \sum_{i=1}^n \delta_{\theta_i}) \quad (C.12)$$

## 2425 C.1 Gibbs Sampling of Parameters

2426 Algorithm, we will draw  $\theta_i | \theta_{-i}, y_i$  for all  $i$ .

2427 And that continuously. So, that's how we get theta.

2428 Gibbs sampling requires the conditional probabilities of all entities involved (Geman and  
 2429 Geman, 1984). Gibbs sampling just as other Markov chain Monte Carlo methods generates  
 2430 a sequence of correlated samples. Subsequently, if necessary, the Maximum A Posteriori  
 2431 estimation of a value can be found through picking the mode (most common occurring  
 2432 value) of a parameter.

2433 The derivation of the conditional probabilities of parameters with respect to the remain-  
 2434 ing parameters has been described in the literature (Neal, 2000). Such a derivation uses  
 2435 an important property of the Dirichlet process, namely that it is the conjugate prior of the  
 2436 multinomial distribution. Thanks to conjugacy the following equations have closed-form  
 2437 descriptions. The conditional probabilities are sampled from the base distribution  $G_0$  and  
 2438 the other parameters  $\theta_i$  in the following way:

$$\theta_{n+1} | \theta_1 \dots \theta_{n-1} \sim \frac{1}{\alpha + n} (\alpha G_0 + \sum_{i=1}^n \delta_{\theta_i}) \quad (C.13)$$

2439 If we include the observations themselves, we need to include the likelihood as well:

$$\theta_i | \theta_{-i}, w_i \sim C \left\{ \sum_{j, j \neq i} F(w_i, \theta_j) \delta_{\theta_j} + \alpha H_i \int F(w_i, \theta) dG_0(\theta) \right\} \quad (C.14)$$

2440 The constant  $C$  is a normalization factor to make the above a proper probability density  
2441 (summing to one). The entity  $H_i$  is the posterior density of  $\theta$  given  $G_0$  as prior and  $y_i$  as  
2442 observation. The notation  $\theta_{-i}$  describes the set of all parameters  $\Theta$  with  $\theta_i$  excluded. The  
2443 integral over  $dG_0(\theta)$  is a Lebesgue-Stieltjes integral that weighs the contribution of  $F(w_i, \theta)$   
2444 with the base distribution  $G_0(\theta)$ .

2445 Equation C.14 can be used to perform inference directly with all (non-unique) parameters  
2446  $\theta_i$  tied to observations  $w_i$ . Details on inference will be provided in Sect. ??.

## GLOSSARY

2447

2448

2449

2450 **burn-in** running a Markov chain Monte Carlo for a while before starting to sample from it,  
2451 so the results are not depending on its initial random starting position. 43

2452 **collapsed Gibbs sampling** Rao-Blackwellized Gibbs sampling. Certain sampling steps are  
2453 replaced by steps where one or more variables are integrated out. This is can be thanks  
2454 to analytic descriptions that arise from the use of conjugate priors. 43

2475		(compare with Fig. 2.6). Top: $\alpha$ , the concentration parameter of the Dirichlet	
2476		process. Bottom, left to right: $w_i$ , the observation, an individual point in a	
2477		2D space; $\theta_i$ , the parameters (intercept, slope) of the line belonging to ob-	
2478		servation $w_i$ ; $H$ , the base distribution from which line parameter values are	
2479		sampled. . . . .	49
2480	3.2	The Infinite Line Model in the stick-breaking representation (compare with	
2481		Fig. 2.6). From left to right: $\alpha$ , the concentration parameter of the Dirichlet	
2482		process; $(\phi_1, \dots, \phi_k)$ , the partition of points over lines; $z_i$ , the assignment	
2483		parameters that link observation $w_i$ with line $k$ ; $w_i$ , the observation, an indi-	
2484		vidual point with $x$ and $y$ coordinates; $\theta_k$ , the parameters of line $k$ ; $\lambda_0$ , the	
2485		base measure from which the line parameter values are sampled. . . . .	55
2486	3.3	The performance of Algorithm 1 with respect to clustering is measured using	
2487		the Rand Index, the Adjusted Rand Index, the Mirvin metric, and the Hubert	
2488		metric. A figure of 1 means perfect clustering for all metrics, except Mirvin's	
2489		where 0 denotes perfect clustering. . . . .	58

2490	3.4	The performance of Algorithm 2 with respect to clustering is measured using	
2491		the Rand Index, the Adjusted Rand Index, the Mirvin metric, and the Hubert	
2492		metric. A figure of 1 means perfect clustering for all metrics, except Mirvin's	
2493		where 0 denotes perfect clustering. . . . .	59
2494	3.5	One of the Gibbs steps in the inference of two particular lines. The points	
2495		are more or less distributed according to the lines, but one line exists out of	
2496		two large clusters. The line coordinates are visualized by a double circle. The	
2497		x-coordinate is the y-intercept of the line, the y-coordinate is the slope. . . . .	60
2498	3.6	The assignment of a line to a single point. There are three clusters found,	
2499		rather than only the obvious two. . . . .	61
2500	4.1	Sampling of Pareto pairs. The parameters are $\lambda_m = 2$ , $\lambda_n = -2$ , $k = 5$ , and	
2501		we have sampled $N = 1000$ pairs. . . . .	64
2502	4.2	Consider the data uniformly distributed on a line segment and a symmetric	
2503		Pareto prior for both the endpoints, then we can update the estimate for the	
2504		endpoints given the data as visualized. Each subfigure shows an adjustment	
2505		of the endpoints given more data points (1, 3, 10, and 100 data points). . . . .	65
2506	4.3	The Bayesian linear regression model for multiple line segments in plate no-	
2507		tation is the same as for the Infinite Line Model. The Dirichlet process is de-	
2508		defined at the left with concentration parameter $\alpha$ . It generates the partitions	
2509		$(\pi_1, \dots, \pi_k)$ with assignment parameters $z_i$ that denote which observation $w_i$	
2510		belongs to which cluster $k$ . The cluster is summarized through the parame-	
2511		ter set $\theta_k$ and has $\lambda_0$ as its hyperparameter. The parameter set $\theta_k$ includes	
2512		parameters that signify the line itself such as slope and y-intercept, plus the	
2513		parameters that denote the extend of the segment. . . . .	65
2514	4.4	Line segments generated through a Dirichlet Process. The Dirichlet process	
2515		itself is again the same. But now four parameters are generated. A normal-	
2516		inverse-Wishart distribution is used to generate the center of the line segment,	
2517		and an inverse-Wishart distribution to generate one of the endpoints of the	
2518		line segments (the other end point is mirrored through its center). Points	
2519		are generated normally over the line segments, with an additional Gaussian	
2520		component to indicate the deviation from the line segment from the normal-	
2521		inverse-Wishart. . . . .	66
2522	4.5	Line segments generated through a Dirichlet Process. Compared to Fig. 4.4	
2523		the points are generated uniformly over the line segments: points are not	
2524		generated outside of the line segments. . . . .	67
2525	4.6	Bayesian point estimates of the sampling process with varying outcomes. . . . .	68
2526	4.7	Segment detection performs much worse than line detection across all three	
2527		clustering performance indicators. Perfect clustering is indicated by 1.0 for	
2528		Rand Index, Adjusted Rand Index, and Hubert. . . . .	69
2529	5.1	Dyadic vs triadic MCMC . . . . .	76
2530	5.2	Two examples of fitting a mixture of lines to data items scattered over a two-	
2531		dimensional space. The lines drawn are inferred using one of the methods in	
2532		this chapter. The lines are not the ground truth, but are meant to demonstrate	
2533		the typical errors made by fitting methods. Note for example that there are	
2534		mistakes in both the assignment of points to lines as well as the line param-	
2535		eters (slope and intercept). . . . .	80

2536	5.3	The same results as in Table 5.1, but visualized in a violin plot. The distribution over metric values are displayed in a vertical fashion. From left to right the distribution shifts to one, signifying better clustering performance. . . . .	81

LIST OF TABLES

2551	2.1	Structures and Processes . . . . .	25
2552	2.2	Levy measure . . . . .	26
2553	2.3	Exchangeable structures . . . . .	27
2554	5.1	The purity, rand index, and adjusted rand index establishing the quality of the clustering method. The closer the values to one, the better the method performed. The purity metric assigns high values to clusters that do not have data points from other clusters (but does not penalize the number of clusters). The rand index index computes similarity between clusters taking false negatives and false positives into account. The adjusted rand index accounts for chance. The adjusted rand index is most useful in our comparison. . . . .	81
2561	7.1	Example of the type of data about the timing of exercising. A person is represented by row, her preferences by column. There is not a predefined number of users or groups of users. . . . .	91
2562	7.2	Top row: A sequence of cluster indices indicates the ground truth. Each cluster index represents a multi-modal Von-Mises-Uniform distribution with different parameters $\theta$ . Bottom row: A sequence of cluster indices that are the result of the described algorithm. Each cluster index represents again a multi-modal Von-Mises distribution. Errors would be represented by an inconsistent mapping from the top row to the bottom row. . . . .	95
